<td>1. Doerr CH, Allen MS, Nichols FC, 3rd, Ryu JH. Etiology of chylothorax in 203 patients. <em>Mayo Clin Proc.</em> 2005;80(7):867-870.</td>
<td>Review/Other-Dx</td>
<td>203 patients</td>
<td>To characterize the etiology of chylothorax in patients encountered at a single tertiary referral center and to compare the findings with those from previous studies.</td>
<td>We identified 203 patients with chylothorax; 92 were females (male-female ratio, 1.21). The median age was 54.5 years (range, 21 weeks’ gestation to 93 years). Dyspnea, the most common presenting symptom, occurred in 98 (56.6%) of 173 patients in whom initial symptoms were recorded, whereas 64 (37.0%) had no respiratory symptoms. Median duration of symptoms before diagnosis was 7.5 weeks (range, 1 day to 4.5 years). Causes of chylothorax included surgery or trauma in 101 patients (49.8%), various medical conditions in 89 (43.8%), and unknown in 13 (6.4%). Among surgical procedures, esophagectomy (29 patients) and surgery for congenital heart disease (28 patients) were the most common causes of chylothorax. Among medical conditions, lymphoma (23 patients), lymphatic disorders (19 patients), and chylous ascites (16 patients) were the most common causes.</td>

<td>2. Maldonado F, Cartin-Ceba R, Hawkins FJ, Ryu JH. Medical and surgical management of chylothorax and associated outcomes. <em>Am J Med Sci.</em> 2010;339(4):314-318.</td>
<td>Observational-Tx</td>
<td>74 patients</td>
<td>To assess the modes of management for chylothorax in 74 adult patients (≥18 years old) and associated outcomes.</td>
<td>Initial treatment approach was nonsurgical in 57 patients (77%) but a surgical procedure (pleurodesis, TD ligation, and/or surgical repair) was eventually performed in 44 patients (59%). The rate of resolution with initial treatment measures was significantly worse for patients with nontraumatic chylothorax compared with those with traumatic causes (27% vs 50%, <em>P</em>=0.048). Even after additional therapeutic maneuvers including surgery, chylous effusion recurred more commonly in nontraumatic chylothorax when compared with the traumatic group (50% vs 13%, respectively, <em>P</em>&lt;0.001).</td>

<td>Maldonado F, Hawkins FJ, Daniels CE, Doerr CH, Decker PA, Ryu JH. Pleural fluid characteristics of chylothorax. <em>Mayo Clin Proc.</em> 2009;84(2):129-133.</td>
<td>Review/Other-Dx</td>
<td>74 patients</td>
<td>To determine the biochemical parameters of chylosous pleural fluids and better inform current clinical practice in the diagnosis of chylothorax.</td>
<td>The study consisted of 37 men (50%) and 37 women (50%), with a median age of 61.5 years (range, 20–93 years). Chylothorax was caused by surgical procedures in 51%. The chylosous pleural fluid appeared milky in only 44%. Pleural effusion was exudative in 64 patients (86%) and transudative in 10 patients (14%). However, pleural fluid protein and lactate dehydrogenase levels varied widely. Transudative chylothorax was present in all 4 patients with cirrhosis but was also seen with other causes. The mean +/- SD triglyceride level was 728 +/- 797 mg/dL, and the mean +/- SD cholesterol value was 66 +/- 30 mg/dL. The pleural fluid triglyceride value was &lt;110 mg/dL in 10 patients (14%) with chylothorax, 2 of whom had a triglyceride value lower than 50 mg/dL.</td>

<td>Observational-Tx</td>
<td>109 patients</td>
<td>To demonstrate the efficacy of a minimally invasive, nonoperative, catheter-based approach to the treatment of traumatic chyle leak.</td>
<td>A total of 106 patients presented with chylothorax, 1 patient presented with chylopericardium, and 2 patients presented with cervical lymphocele. 20 patients (18%) had previous failed TD ligation. In 108/109 patients, a lymphangiogram was successful. Catheterization of the TD was achieved in 73 patients (67%). In 71/73 patients, TDE was performed. Endovascular coils or liquid embolic agent was used to occlude the TD. In 18/33 cases of unsuccessful catheterization, TD needle interruption was attempted below the diaphragm. Resolution of the chyle leak was observed in 64/71 patients (90%) postembolization. Needle interruption of the TD was successful in 13/18 patients (72%). In 17/20 patients who had previous attempts at TD ligation, embolization or interruption was attempted and successful in 15 (88%). The overall success rate for the entire series was 71% (77/109). There were 3 (3%) minor complications.</td>

<td>6. Nadolski GJ, Itkin M. Thoracic duct embolization for nontraumatic chylous effusion: experience in 34 patients. <em>Chest</em>. 2013;143(1):158-163.</td>
<td>Observational-Tx</td>
<td>34 patients</td>
<td>To demonstrate efficacy of TDE in treating nontraumatic chylous effusions.</td>
<td>34 patients (mean age, 59 years; 27 female patients) with nontraumatic chylous effusions underwent TDE. Presentations included 21 unilateral chylothoraces (61.8%), 9 bilateral chylothoraces (26.5%), 2 isolated chylopericardiums (5.9%), and 2 pleural effusions with chylopericardium (5.9%). TDE was technically successful in 24/34 patients (70.6%). The TD could not be catheterized in 4/34 (11.8%). Cisterna chyli was not visualized in 6/34 patients (17.6%), and, thus, TDE was not attempted. Follow-up was available for 32 patients. 4 lymphangiographic patterns were observed: (1) normal TD in 17.6% of patients (6/34), (2) occlusion of TD in 58.8% (20/34), (3) failure to opacify TD in 17.6% (6/34), and (4) extravasation of chyle in 5.9% (2/34). Clinical success varied with the lymphangiographic pattern. The clinical success rate was 16% (1 of 6) in cases of normal TD, 75% (15/20 patients) in occlusions of the TD, 16% (1 of 6) in cases of failure to opacify the TD, and 50% in 2 cases of chyle extravasation. LAG alone cured 2 patients (6.5%).</td>

<td>Observational-Tx</td>
<td>105 patients</td>
<td>To review the indications, technical approach, and clinical outcomes of TDE and TD disruption in patients with symptomatic chylous effusions.</td>
<td>The technical success rate was 79% (95/120); 53 TDEs were performed, resulting in a 72% clinical success rate (n = 38), whereas 42 TD disruptions showed a 55% clinical success rate (n = 23; P=.13). Procedures to treat postpneumonectomy chylous effusions had a success rate of 82% (14/17), compared with 47% (9/19) in postpleurectomy subjects (P&lt;.05). Clinically successful cases had lower 24-, 48-, and 72-hour postprocedural effusion volumes vs clinically unsuccessful cases (P&lt;.05), as well as greater rates of reduction in effusion volume at these time points (P&lt;.05). Clinical success rate in subjects with traumatic effusions was higher than in subjects with nontraumatic effusions (62% [60/97] vs 13% [1 of 8]; P&lt;.05), and 6.7% of subjects (n = 7) experienced minor complications.</td>

<td>10. Platis IE, Nwogu CE. Chylothorax.  <em>Thorac Surg Clin.</em> 2006;16(3):209-214.</td>
<td>Review/Other-Tx</td>
<td>N/A</td>
<td>To review the diagnosis and management of chylothorax.</td>
<td>Chylothorax is a rare complication of pulmonary resection. It requires prompt treatment, which is initially conservative. This treatment consists of drainage, nutritional support, and measures to diminish chyle flow. Surgical intervention is indicated when conservative management is ineffective. Delay in surgical intervention leads not only to serious metabolic, nutritional, and immunologic disturbances from the loss of chyle but also increases the risk for adhesion formation, loculation, organization, and infection of the chylothorax, making subsequent surgical attempts difficult and increasing postoperative morbidity and mortality. Video-assisted thoracic surgery provides a minimally invasive approach for the treatment of chylothorax complicating pulmonary resection. Clipping of the TD or chemical pleurodesis may be performed with minimal morbidity and mortality. Conservative treatment is expensive and fails in most patients who have high-output chylous fistulae. On the other hand, video-assisted thoracic surgery is uniformly effective, is less expensive, and has low morbidity. Indeed, video-assisted thoracic surgery is rapidly becoming the preferred approach for the management of chylothorax complicating pulmonary resection. The need to prevent the occurrence of a chylothorax by careful dissection techniques and liberal clipping of lymphatic vessels particularly in areas of high anatomic risk during the initial operation cannot be overemphasized.</td>

<td>Review/Other-Tx</td>
<td>N/A</td>
<td>To discuss percutaneous LAG-guided cannulation and embolization of the TD.</td>
<td>High-output chylous leak beyond 5 to 7 days of conservative medical treatment should be treated promptly to avoid the risk for nutritional and immunologic depletion. Given the effectiveness and low morbidity of this minimally invasive treatment, this is a reasonable first option before surgical repair of TD leak not responsive to conservative medical treatment.</td>

<td>Review/Other-Tx</td>
<td>11 patients</td>
<td>To describe a cohort of patients with persistent benign chylothorax managed with tunneled indwelling pleural catheters.</td>
<td>11 patients (14 hemithoraces) had persistent benign chylothorax treated with placement of a tunneled indwelling pleural catheter during the inclusion time frame. Etiology of the chylothorax was nontraumatic in 8/11 patients, with the remaining 3 secondary to thoracic surgery. Pleurodesis was achieved in 9/14 hemithoraces, with a median time to pleurodesis of 176 days. All procedures were well tolerated, and no immediate periprocedural complications were reported. 1 serious complication was encountered in the form of a postoperative pulmonary embolism after replacement of an occluded tunneled indwelling pleural catheter, resulting in the patient’s death. 2 patients had transient occlusions of their tunneled indwelling pleural catheters successfully treated with intracatheter thrombolytic therapy. No significant adverse nutritional, hemodynamic or immunologic outcomes were reported during follow-up for any included patient.</td>

<td>Experimental-Tx</td>
<td>11 patients</td>
<td>To prospectively assess the efficacy of percutaneous transabdominal TD catheterization and embolization in the management of patients with high-output chylothoracic effusions.</td>
<td>There were no retroperitoneal ducts suitable for catheterization in 6 patients because of previous abdominal surgery, trauma, or lymphangioleiomyomatosis; the TD was successfully catheterized in 5 patients, a 45% technical success rate. TDE was performed in 4 patients, with cure of effusion in 2. In the other 2 patients, 1 with lymphangioleiomyomatosis and the other with nonchyloous pleural fluid, continued effusion was successfully treated by means of pleurodesis. Of 2 patients with previous TD ligation, 1 was found to have the duct incompletely tied. The authors were surprised to find that previous major abdominal surgery, chronic aortic dissection, and lymphangioleiomyomatosis could obliterate major retroperitoneal lymphatic ducts and the cisterna chyli. Percutaneous study of the TD with aqueous contrast medium was more sensitive than lymphography with iodinated oil. There was no morbidity.</td>

<td>Review/Other-Dx</td>
<td>12 patients</td>
<td>To evaluate the usefulness of LAG and CT in the diagnosis and localization of laceration of the TD in patients with chylothorax or chylous ascites after surgery.</td>
<td>7 patients had abnormal findings on lymphangiograms; 5 with leaks from the TD, 1 with a lymphocele in a nephrectomy bed, and 1 with obstructed intestinal lymphatic vessels after thoracotomy. 5 patients had no evidence of lymphatic leakage. CT in 1 patient with evidence of a leak on LAG showed extravasation of contrast medium into the mediastinum and pleural space. CT in 3 patients with no abnormalities on LAG also showed no abnormalities. 4 of the 5 TD lacerations and the lymphocele were confirmed surgically. The diagnosis of obstructed intestinal lymphatic vessels was supported clinically. 4 of the 5 patients with normal findings on lymphangiograms had resolution of their pleural effusions and no evidence of recurrence during a follow-up period of 1–27 months. 1 patient with normal findings on LAG had an alternative diagnosis established at surgery. Laceration of the TD was accurately diagnosed and localized with LAG, which allowed definitive surgical repair. CT was of little additional value in diagnosing these injuries.</td>

<td>Review/Other-Dx</td>
<td>15 patients</td>
<td>To discuss the clinical value of LAG for intractable spontaneous chylothorax.</td>
<td>12 cases had successful LAG while LAG failed in the other 3 cases. No procedure-related complications occurred. LAG was useful for the diagnosis of lymphatic vessel disease and underlying disease in 6 (50%) cases, but the etiology in the remaining 6 cases (50%) remained uncertain. Signs of leakage or contrast extravasation were directly detected in 5 (42%) patients. Based on the LAG findings, 5 cases underwent surgical intervention with satisfactory results, with 1 recurrence 5 years later. 2 patients had steatorrhea and chyluria after successful TD ligation. 7 cases were treated conservatively, 5 of whom were cured while the other 2 cases had temporary remission of symptoms.</td>

<td>Observational-Dx</td>
<td>27 patients</td>
<td>To evaluate the anatomic and functional images of contrast MR LAG in the diagnosis of limb lymphatic circulation disorders.</td>
<td>Examination of the MRIs after injection of the contrast agent showed enhanced lymphatic channels consistently visualized in all clinical lymphedematous limbs and in 5 contralateral limbs of unilateral lymphedema patients. The speed of flow within the lymphatics of lymphedematous limbs was 0.3 to 1.48 cm/min. Contrast enhancement in inguinal nodes of edematous limbs was significantly less than that of contralateral limbs (<em>P</em>&lt;.01). Dynamic measurement of contrast enhancement showed a remarkable lowering of peak time (<em>P</em>&lt;.01) and peak enhancement (<em>P</em>&lt;.01), and a delay in outflow in inguinal nodes of affected limbs compared with that of control limbs. Postcontrast MRI also depicted varied distribution patterns of lymphatics and abnormal lymph flow pathways within lymph nodes in the limbs with lymphatic circulation disorders.</td>

ACR Appropriateness Criteria®

Evidence Table Key

Study Quality Category Definitions

- **Category 1** The study is well-designed and accounts for common biases.
- **Category 2** The study is moderately well-designed and accounts for most common biases.
- **Category 3** There are important study design limitations.
- **Category 4** The study is not useful as primary evidence. The article may not be a clinical study or the study design is invalid, or conclusions are based on expert consensus. For example:
  
  a) the study does not meet the criteria for or is not a hypothesis-based clinical study (e.g., a book chapter or case report or case series description);
  
  b) the study may synthesize and draw conclusions about several studies such as a literature review article or book chapter but is not primary evidence;
  
  c) the study is an expert opinion or consensus document.
- **M** = Meta-analysis

Abbreviations Key

- **Dx** = Diagnostic
- **Tx** = Treatment

CT = Computed tomography

LAG = Lymphangiography

MDCT = Multidetector computed tomography

MRI = Magnetic resonance imaging

SD = Standard deviation

SPECT = Single-photon-emission computed tomography

TD = Thoracic duct

TDE = Thoracic duct embolization
