<td>1. Echeverria AB, Branco BC, Goshima KR, Hughes JD, Mills JL, Sr. Outcomes of endovascular management of acute thoracic aortic emergencies in an academic level 1 trauma center. Am J Surg. 2014;208(6):974-980; discussion 979-980.</td>
<td>Observational-Tx</td>
<td>22 patients</td>
<td>To evaluate the experience and outcomes in patients presenting with acute aortic catastrophes in a moderate-volume center.</td>
<td>During the study period, 51 patients underwent TEVAR; 22 cases (43.1%) were performed emergently (11 patients [50.0%] traumatic aortic injury; 4 [18.2%] ruptured descending thoracic aneurysm; 4 [18.2%] complicated type B dissection; 2 [9.1%] penetrating aortic ulcer; and 1 [4.5%] aortoenteric fistula). Overall, 72.7% (n = 16) were male with a mean age of 54.8 +/- 15.9 years. 19 patients (86.4%) required only a single TEVAR procedure, whereas 2 (9.1%) required additional endovascular therapy, and 1 (4.5%) open thoracotomy. 4 traumatic aortic injury patients required exploratory laparotomy for concomitant intra-abdominal injuries. During a mean hospital length of stay of 18.9 days (range, 1 to 76 days), 3 patients (13.6%) developed major complications. In-hospital mortality was 27.2%, consisting of 6 deaths from traumatic brain injury (1); exsanguination in the operating room before repair could be achieved (2); bowel ischemia (1) and multisystem organ failure (1); and family withdrawal of care (1). A stepwise logistic regression model identified 24-hour packed red blood cell requirements ≥4 units, admission mean arterial pressure &lt;60 mm Hg, and 24-hour fresh frozen plasma to packed red blood cell ratio &lt;1.15 as independent risk factors for death in this cohort. During a mean follow-up of 369 days (range, 35 to 957 days), no subsequent major complications or deaths occurred. All patients underwent serial CTA surveillance, and no device-related problems were identified during intermediate follow-up.</td>

<td>2. Shennib H, Rodriguez-Lopez J, Ramaiah V, et al. Endovascular management of adult coarctation and its complications: intermediate results in a cohort of 22 patients. European Journal of Cardio-Thoracic Surgery. 2010;37(2):322-327.</td>
<td>Review/Other-Tx</td>
<td>10 patients with recently discovered de novo coarctations were treated with balloon-expandable stents, and an endoluminal graft was used in 1 additional patient. In the other 11 patients with recurrent lesions, 3 underwent repeat balloon dilation and stenting; 8 patients with recurrence and aneurysms received endoluminal grafts. The gradients across the coarctation decreased from 49 + 16 to 4 + 7 mmHg (P=0.001), and the diameters increased from 10 + 4 to 19 + 4mm (P=0.001). In 5 of the 8 patients (63%) with aneurysms, the endoluminal graft covered the subclavian artery, and a carotid-subclavian bypass was necessary. 2 patients required iliac artery access. No early major complications occurred. At mean follow-up of 31 + 15.6 months, 1 patient with type II leak resolved spontaneously and another developed neck dilation and type I leak, requiring a second endoluminal graft placement. All patients except 1 had improvements in symptoms and better hypertension control.</td>

<td>5. Carpenter SW, Kodolitsch YV, Debus ES, et al. Acute aortic syndromes: definition, prognosis and treatment options. The Journal of Cardiovascular Surgery. 2014;55(2 Suppl 1):133-144.</td>
<td>Review/Other-Tx</td>
<td>N/A</td>
<td>To present the definition, prognosis, and treatment options for AAS.</td>
<td>AAS are life-threatening vascular conditions of the thoracic aorta presenting with acute pain as the leading symptom in most cases. The incidence is approximately 3–5/100,000 in western countries with increase during the past decades. Clinical suspicion for AAS requires immediate confirmation with advanced imaging modalities. Initial management of AAS addresses avoidance of progression by immediate medical therapy to reduce aortic shear stress. Proximal symptomatic lesions with involvement of the ascending aorta are surgically treated in the acute setting, whereas acute uncomplicated distal dissection should be treated by medical therapy in the acute period, followed by surveillance and repeated imaging studies. Acute complicated distal dissection requires urgent invasive treatment and TEVAR has become the treatment modality of choice because of favorable outcomes compared to open surgical repair. IMH, penetrating aortic ulcers, and traumatic aortic injuries of the descending aorta harbor specific challenges compared to aortic dissection and treatment strategies are not as uniformly defined as in aortic dissection. Moreover these lesions have a different prognosis. Once the acute period of aortic syndrome has been survived, a lifelong medical treatment and close surveillance with repeated imaging studies is essential to detect impending complications which might need invasive treatment within the short-, mid- or long-term.</td>

<td>Observational-Tx</td>
<td>151 patients</td>
<td>To compare the long-term outcomes of TEVAR with the 3 commercially available stents grafts for thoracic aortic aneurysms to results in control subjects undergoing open surgery.</td>
<td>During the study period (1995-2007) 106 patients were enrolled in TEVAR trials and there were 45 open controls. TEVAR patients were older and had significantly more comorbidities including diabetes and renal failure. TEVAR patients had 2.3 +/- 1.3 devices implanted. Mortality (2.6% TEVAR, 6.7% open; <em>P</em>=.1), paralysis/paraparesis (3.9% TEVAR, 7.1% open; <em>P</em>=.2), and prolonged intubation &gt;24 hours (9% TEVAR, 24% open; <em>P</em>=.02) tended to be more common in the open controls. Overall survival at 10 years was similar between groups (log rank <em>P</em>=.5). Multivariate predictors of late mortality included age, chronic obstructive pulmonary disease, diabetes, and chronic renal failure. Use of TEVAR vs open surgery did not influence mortality (hazard ratio, 0.9 95% CI, 0.4–1.6). Over 5 years of radiographic follow-up in the TEVAR group, mean aortic diameter decreased from 61 to 55 mm. Freedom from reintervention on the treated segment was 85% in TEVAR patients at 10 years.</td>

<td>9. Prescott-Focht JA, Martinez-Jimenez S, Hurwitz LM, et al. Ascending thoracic aorta: postoperative imaging evaluation. Radiographics. 2013;33(1):73-85.</td>
<td>Review/Other-Tx</td>
<td>N/A</td>
<td>To review several open-repair techniques and their indications, as well as their normal and abnormal postoperative appearances at CTA.</td>
<td>Several abnormalities of the ascending aorta and aortic arch often require surgery, and various open techniques may be used to reconstruct the aorta, such as the Wheat procedure, in which both an ascending aortic graft and an aortic valve prosthesis are implanted; the Cabrol and modified Bentall procedures, in which a composite synthetic ascending aorta and aortic valve graft are placed; the Ross procedure, in which the aortic valve and aortic root are replaced with the patient’s native pulmonary valve and proximal pulmonary artery; valve-sparing procedures such as the T. David-V technique, which leaves the native aortic valve intact; and more extensive arch repair procedures such as the elephant trunk and arch-first techniques, in which interposition or inclusion grafts are implanted, with or without replacement of the aortic valve. Normal postoperative imaging findings, such as hyperattenuating felt pledgets, prosthetic conduits, and reanastomosis sites, may mimic pathologic processes. Postoperative complications seen at CTA that require further intervention include pseudoaneurysms, anastomotic stenoses, dissections, and aneurysms.</td>

<td>Observational-Tx</td>
<td>50 patients</td>
<td>To report long-term outcomes of TEVAR for acute (≤2 weeks from symptom onset) complicated type B dissection.</td>
<td>Indications for intervention included rupture in 10 (20%), malperfusion in 24 (48%), and/or refractory pain/impending rupture in 17 (34%). 1 patient (2%) had both rupture and malperfusion indications. 10 (20%) patients required 1 or more adjunctive procedures, in addition to TEVAR, to treat malperfusion syndromes. In-hospital and 30-day rates of death were both 0%; 30-day/in-hospital rates of stroke, permanent paraplegia/paraparesis, and new-onset dialysis were 2% (n = 1), 2% (n = 1), and 4% (n = 2), respectively. Median follow-up was 33.8 months [interquartile range, 12.3–56.6 months]. Overall survival at 5 and 7 years was 84%, with no deaths attributable to aortic pathology. 13 (26%) patients required a total of 17 reinterventions over the study period for type I endoleak (n = 5), metachronous aortic pathology (n = 5), persistent false lumen pressurization via distal fenestrations (n = 4), type II endoleak (n = 2), or retrograde acute type A aortic dissection (n = 1). Median time to first reintervention was 4.5 months (range, 0 days–40.3 months). Of the 17 total reinterventions, 6 (35%) were performed using open techniques and 11 (65%) with endovascular or hybrid methods; there was no difference in survival between patients who did or did not require reintervention.</td>

<td>13. Lavingia KS, Ahanchi SS, Redlinger RE, Udgiri NR, Panneton JM. Aortic remodeling after thoracic endovascular aortic repair for intramural hematoma. <em>J Vasc Surg.</em> 2014;60(4):929-935; discussion 935-926.</td>
<td>Review/Other-Tx</td>
<td>44 patients</td>
<td>To study the effect of TEVAR for IMH on aortic remodeling.</td>
<td>During the 6-year period, 44 patients underwent TEVAR for IMH. 25 patients had an IMH with concomitant penetrating atherosclerotic ulcer. There were 25 (57%) female patients. Mean age was 71 +/- 11 years and 40 (91%) patients had hypertension. Operative indications included intractable pain in 31 (70%), rapidly progressing IMH or conversion to dissection in 13 (30%), rupture in 10 (23%), and uncontrolled hypertension in 6 (14%). Technically successful TEVAR was performed in all patients with 42 (95%) reporting complete relief of symptoms. The 30-day mortality rate was 5% with a 5% rate of permanent paraplegia or paraparesis. At a mean follow-up of 26 months, there were no additional aortic-related deaths and overall survival was 80% with a reintervention rate of 11%. For our imaging analysis, 10 patients were excluded because of lack of follow-up imaging beyond 30 days. At a mean follow-up of 13 months, all measured data points were statistically improved from before to after TEVAR: thickness of IMH (12 mm vs 4 mm; $P=.01$), mean true lumen diameter (35 mm vs 37 mm; $P=.04$), mean total aortic diameter (47 mm vs 42 mm; $P=.02$), total aortic diameter/true lumen diameter ratio (1.35 vs 1.14; $P&lt;.01$), and IMH volume (103 cm3 vs 14 cm3; $P&lt;.01$). The mean Delta in total aortic diameter/true lumen diameter ratio from before to after TEVAR for the reintervention group was Delta0.14, and the mean Delta in total aortic diameter/true lumen diameter ratio for the nonreintervention group was Delta0.29 ($P=.05$). Analysis of patients with isolated IMH and those with concomitant penetrating atherosclerotic ulcer revealed no statistical differences.</td>

<td>20. Brown CR, Greenberg RK, Wong S, et al. Family history of aortic disease predicts disease patterns and progression and is a significant influence on management strategies for patients and their relatives. <em>J Vasc Surg.</em> 2013;58(3):573-581.</td>
<td>Observational-Dx</td>
<td>426 patients</td>
<td>To evaluate the influence of a family history of aortic disease with respect to the pattern and distribution of aortic aneurysms in a given patient.</td>
<td>Of the 555 patients who were alive and returning for follow-up, we obtained 426 (77%) family histories. 3D imaging studies were used to identify the presence of aneurysms; 36% (155/426) of patients had a family history of aortic aneurysms and 5% (21/155) had isolated intracranial aneurysms. A logistic regression model was used to compare aortic morphology between patients with a positive or negative family history for aneurysms. Patients with a positive family history of aortic aneurysms were younger at their initial aneurysm (63 vs 70 years; ( P &lt; .0001 )), more frequently had proximal aortic involvement (root: OR, 5.4; ( P &lt; .0001 ); ascending: OR, 2.9; ( P &lt; .001 ); thoracic: OR, 2.2; ( P = .01 )) with over 50% of family history patients ultimately developing suprarenal aortic involvement (( P = .0001 )) and had a greater incidence of bilateral iliac artery aneurysm (OR, 1.8; ( P = .03 )).</td>

<td>Observational-Tx</td>
<td>10 patients</td>
<td>To evaluate the effectiveness of endovascular stent grafting for surgical management of aortic pseudoaneurysm in patients with Behcet’s disease.</td>
<td>From 1998 to 2012, 10 patients (8 male, 2 female; median age, 39) with Behcet’s disease and aortic pseudoaneurysm were treated with endovascular stent grafting at this institution. 90% of these patients received immunosuppressive therapy before and after surgical treatment. The median follow-up period was 57 months (interquartile range, 43–72). The locations of the 12 pseudoaneurysms treated in this cohort were infrarenal abdominal aorta (7), descending thoracic aorta (4), and aortic arch (1). Median pseudoaneurysm size was 4.5 cm (interquartile range, 3.4–5.9). At long-term follow-up, complete resolution of the aortic pseudoaneurysm was noted in all patients. No endoleaks occurred. Newly developed pseudoaneurysm at the distal margin of the stent graft was noted in 1 patient 17 months after the stent graft procedure. 1 patient required a subsequent stent graft placement for an expanding pseudoaneurysm of the subclavian artery. No patient deaths occurred during the follow-up period.</td>

<td>28. Cochennec F, Kobeiter H, Gohel MS, et al. Impact of intraoperative adverse events during branched and fenestrated aortic stent grafting on postoperative outcome. <em>J Vasc Surg.</em> 2014;60(3):571-578.</td>
<td>Observational-Tx</td>
<td>113 patients</td>
<td>To report our experience of intraoperative adverse events during fenestrated and branched stent grafting and to analyze the impact on clinical outcomes.</td>
<td>During the study period, 113 consecutive elective patients underwent fenestrated or branched stent grafting. Indications for treatment were asymptomatic complex abdominal aortic aneurysms (n = 89) and thoracoabdominal aortic aneurysms (n = 24). Stent grafts included fenestrated (n = 79) and branched (n = 17) Cook stent grafts (Cook Medical, Bloomington, Ind), Ventana (Endologix, Irvine, Calif) stent grafts (n = 9), and fenestrated Anaconda (Vascutek Terumo, Scotland, UK) stent grafts (n = 8). In-hospital mortality rates for the complex abdominal aortic aneurysm and thoracoabdominal aortic aneurysm groups were 6.7% (6/89) and 12.5% (3/24), respectively. 28 moderate to severe complications occurred in 21 patients (18.6%). Spinal cord ischemia was recorded in 6 patients, 3 of which resolved completely. A total of 37 intraoperative adverse events were recorded in 34 (30.1%) patients (22 complex abdominal aortic aneurysms and 12 thoracoabdominal aortic aneurysms). Of 37 intraoperative adverse events, 15 (40.5%) resulted in no clinical consequence in 15 patients; 17 (45.9%) were responsible for moderate to severe complications in 16 patients, and 5 (13.5%) led to death in 4 patients. The composite end point death/nonfatal moderate to severe complication occurred more frequently in patients with intraoperative adverse events compared with patients without intraoperative adverse events (20/34 vs 12/79; <em>P</em> &lt; .0001).</td>

<td>29. Eagleton MJ, Shah S, Petkosev D, Mastracci TM, Greenberg RK. Hypogastric and subclavian artery patency affects onset and recovery of spinal cord ischemia associated with aortic endografting. <em>J Vasc Surg.</em> 2014;59(1):89-94.</td>
<td>Observational-Tx</td>
<td>1251 patients</td>
<td>To evaluate factors affecting outcomes from spinal cord ischemia associated with endovascular aortic aneurysm repair.</td>
<td>Spinal cord ischemia occurred in 2.8% (n = 36) of patients: abdominal aortic aneurysm, 0.3%, juxtarenal, 0.4%, thoracic aortic aneurysm, 4.6%, and thoracoabdominal aortic aneurysm, 4.8%). 4 (11%) required carotid-subclavian bypass prior to endografting, and 2 underwent coverage of the left subclavian artery. Unilateral hypogastric artery occlusion was present in 11 (31%) patients prior to endograft placement, and 3 had bilateral occlusions. An additional 7 patients had occlusion of at least 1 hypogastric artery during surgery. Spinal cord ischemia was apparent immediately in 15 (42%) patients. Immediate onset of symptoms was observed in 73% of patients with at least 1 occluded collateral bed but in only 24% of those with patent collateral beds (<em>P</em>=.021). Of those presenting in a delayed fashion, 9 (43%) had a clear precipitating event prior to onset of spinal cord ischemia (hypotension, n = 6, and segmental artery drain removal, n = 3). Recovery occurred in 24 (67%) patients, most within 7 days. Immediate presentation was a negative predictor of recovery (<em>P</em>=.025), as was occlusion of at least 1 collateral bed (<em>P</em>=.035). Mean follow-up was 22 +/- 4 months with 30-day and 1-year survival of 92 +/- 4.6% and 56 +/- 8.3%. Survival was only 36% at 3 months in those with permanent spinal cord ischemia compared with 92% (<em>P</em>&lt;.001) in those with temporary symptoms.</td>

<td>32. Faure EM, Canaud L, Agostini C, et al. Reintervention after thoracic endovascular aortic repair of complicated aortic dissection. <em>J Vasc Surg.</em> 2014;59(2):327-333.</td>
<td>Observational-Tx</td>
<td>41 patients</td>
<td>To assess predictive factors for reintervention after TEVAR for complicated aortic dissection.</td>
<td>Between 2000 and 2011, 41 patients underwent TEVAR for a complicated aortic dissection involving the descending thoracic aorta. Primary indications included aneurysm &gt;55 mm in 24, rapid aneurysmal enlargement or impending rupture in 6, saccular aneurysm &gt;20 mm in 1, malperfusion in 1, intractable chest pain in 3, and rupture in 6. Technical success was achieved in 100%. The 30-day mortality rate was 5% (n = 2). 14 secondary procedures were performed in 13 patients (32%) for indications of device migration in 2, proximal type I endoleak in 5, distal type I endoleak in 2, type II endoleak in 1, aneurysmal evolution of the descending thoracic aorta in 2, aneurysmal expansion of the dissected abdominal aorta in 1, and retrograde dissection in 1. Multivariate analysis demonstrated that oversizing ≥20% (OR, 16; <em>P</em> = .011), bare-spring stent in the proximal landing zone of the stent graft (OR, 12; <em>P</em> = .032), and anticoagulant therapy (OR, 78; <em>P</em> = .03) were significant factors for reintervention. On univariate analysis, large aneurysm was a risk factor for reintervention (<em>P</em> = .002), whereas complete false lumen thrombosis at the stent graft level was protective (<em>P</em> &lt; .05).</td>

<td>Review/Other-Tx</td>
<td>32 patients</td>
<td>To examine long-term results of TEVAR for this disorder including examination of anatomic features associated with TEVAR outcomes.</td>
<td>The mean interval from dissection to TEVAR was 32 +/- 44 months (range, 1 to 146 months). There were no 30-day or in-hospital deaths, strokes, or paraplegia. During a 54-month median follow-up, there were no aortic-related deaths. Significant thoracic aneurysm sac regression (&gt;1 cm) in the intervened segment was observed in 89%. Thoracic remodeling was not correlated with the number of visceral vessels arising from the true lumen or the number or size of residual distal fenestrations; failure of thoracic remodeling was associated with fenestrations distal to the endograft(s) in the descending thoracic aorta, most often stent graft-induced new entry tears. Complete resolution of the thoracic and abdominal false lumen after TEVAR was observed in 15.6% (n = 5). All patients in this group had all visceral vessels arising from the true lumen and fewer than 3 residual distal fenestrations.</td>

<td>Observational-Tx</td>
<td>32 patients</td>
<td>To evaluate the morphology of stent graft and aorta remodeling and the volumetric changes in these patients after successful TEVAR.</td>
<td>Aortic stent grafts remodeled progressively, with inlet area increasing 4.4%, 10.1%, and 14.2% and outlet area increasing 42.6%, 67.2%, and 72.3%, respectively, at 6, 12, and 36 months. True lumen volume increased progressively in group A (114 to 174 mL) and group B (124 to 190 mL) from baseline to 36 months. False lumen volume decreased in group A (150 to 88 mL) and group B (351 to 250 mL), whereas thrombus load in the false lumen increased from 73% to 80% in group A and 84% to 87% in group B in 3 years. 8 patients (4 in each group) showed an increase in total aortic volume of &gt;10%, 12 showed a static volume, and 12 showed shrinkage. Aortic volume change had no relationship to pathology, stent graft sizing, and thrombus load but was positively associated with the placement of a longer graft. A small but progressive distal migration of stent grafts was noted in all patients (3.1, 4.5, and 5.1 mm at 6, 12, and 36 months) but was more prominent in shorter stent grafts (≤162 mm). No deaths, rupture, or secondary interventions occurred during follow-up.</td>

<td>Observational-Dx</td>
<td>50 subjects</td>
<td>To examine the impact of methodological variance on aortic quantification.</td>
<td>50 subjects were studied. Aortic size differed between axial and double oblique at all locations ($P \leq 0.001$), with magnitude greatest at the sinotubular junction (4.8+/-1.1 vs 4.0+/-1.0 cm, $P&lt;0.001$). The difference between axial and double oblique correlated with aortic angular displacement ($r=0.37, P&lt;0.01$), which was threefold larger at the sinotubular junction (37+/−12 degrees) than the ascending aorta (12+/−5 degrees; $P&lt;0.001$). At all locations, aortic area calculated using double oblique yielded smaller differences with planimetry than axial ($P&lt;0.05$). Double oblique and planimetry yielded equal prevalence (24%) of subjects eligible for prophylactic thoracic aortic aneurysms repair based on area-height cutoff, whereas axial prevalence was higher (44%; $P=0.006$). Using a linear cutoff, axial yielded over a twofold greater prevalence of surgically eligible subjects (56%) than did double oblique (24%; $P&lt;0.001$).</td>

<td>44. Tolenaar JL, van Keulen JW, Trimarchi S, et al. Number of entry tears is associated with aortic growth in type B dissections. <em>Ann Thorac Surg.</em> 2013;96(1):39-42.</td>
<td>Observational-Dx</td>
<td>60 patients</td>
<td>To investigate whether the number of identifiable entry tears in acute type B aortic dissection patients is associated with aortic growth.</td>
<td>Included were 60 patients who presented with 243 dissected segments. Mean growth rates during follow-up (median, 23.2; range, 3 to 132 months) were significantly higher in patients with 1 entry tear (5.6 +/- 8.9 mm) than in those with 2 (2.1 +/- 1.7 mm; <em>P</em>=0.001) and 3 entry tears (mean 2.2 +/- 4.1; <em>P</em>=0.010). The distance of the primary entry tear from the left subclavian artery did not have an effect on the aortic growth rate (median, 38; interquartile range, 24 to 137 mm; <em>P</em>=0.434).</td>

<td>45. Mehta M, Darling RC, 3rd, Taggert JB, et al. Outcomes of planned celiac artery coverage during TEVAR. <em>J Vasc Surg.</em> 2010;52(5):1153-1158.</td>
<td>Review/Other-Tx</td>
<td>31 patients</td>
<td>To report our experience of planned celiac artery coverage during endovascular repair of complex thoracic aortic aneurysms.</td>
<td>31 of 228 (14%) patients with TEVAR required celiac artery interruption; 24 (77%) had demonstrable collaterals to the superior mesenteric artery. 12 (39%) of 31 patients underwent additional partial superior mesenteric artery coverage by stent graft, and proximal superior mesenteric artery stent. The majority of patients were females (n=20, 65%), the mean age was 74 years (range 55–87 years), and the mean thoracic aortic aneurysms size was 6.5 cm. Postoperative complications included visceral ischemia in 2 (6%) patients, paraplegia in 2 (6%) patients, and death in 2 (6%) patients. All type 1b endoleaks (n=2, 6%) and type 2 endoleaks via retrograde flow from the celiac artery (n=3, 10%) were successfully treated by transfemoral coil embolization. Over a mean follow-up of 15 months, there have been no other complications of mesenteric ischemia, spinal cord ischemia, superior mesenteric artery in-stent stenosis, or conversion to open surgical repair.</td>

<td>46. Hsu HL, Chen CK, Chen PL, et al. The impact of bird-beak configuration on aortic remodeling of distal arch pathology after thoracic endovascular aortic repair with the Zenith Pro-Form TX2 thoracic endograft. <em>J Vasc Surg</em>. 2014;59(1):80-88.</td>
<td>Observational-Tx</td>
<td>19 patients</td>
<td>To analyze the morphologic changes, conformability, and angulation factors in patients who underwent stainless steel-based stent graft repair of thoracic aortic pathology.</td>
<td>The treated diseases included chronic type B aortic dissection in 17 patients and degenerative aneurysms in 21. Significant arch angle transformation was noted at the zone 2 level between the Pro-Form and Z-Trak treated groups (150 degrees +/- 11 degrees vs 158 degrees +/- 6 degrees; <em>P</em> = .033) and left subclavian artery level (152 degrees +/- 12 degrees vs 160 degrees +/- 8 degrees; <em>P</em> = .031) during 1 year of follow-up. The bird-beak configuration was detected in 6 patients (32%) in the Pro-Form group and in 11 (58%) in the Z-Trak group (<em>P</em> = .096) at 1 month, and in 6 (32%) in the Pro-Form group and in 14 (74%) in the Z-Trak group (<em>P</em> = .022) at 12 months. The mean bird-beak angle was significantly less in Pro-Form-treated patients at 1 month (5 degrees +/- 9 degrees vs 15 degrees +/- 13 degrees; <em>P</em> = .019) and at 1 year (6 degrees +/- 10 degrees vs 18 degrees +/- 15 degrees; <em>P</em> = .033). In the Pro-Form platform, a preoperative zone 2 angle &lt; 151.1 degrees was a better estimation of the presence of a postoperative bird-beak configuration, with a sensitivity of 86% and specificity of 83%.</td>

<td>49. Bisdas T, Donas KP, Bosiers MJ, Torsello G, Austermann M. Custom-made versus off-the-shelf multibranched endografts for endovascular repair of thoracoabdominal aortic aneurysms. <em>J Vasc Surg.</em> 2014;60(5):1186-1195.</td>
<td>Observational-Tx</td>
<td>46 patients</td>
<td>To compare early outcomes between the custom-made and the new off-the-shelf multibranched endograft (mhEVAR, t-branch; Cook Medical, Bloomington, Ind) for the endovascular repair of thoracoabdominal aortic aneurysms.</td>
<td>Technical success was 100% in both groups. The 30-day mortality was 8% in group A (n = 2) and 0% in group B (<em>P</em> = .51). Survival rates at 6 months were 71% in group A (mean follow-up, 13 +/- 11 months) and 94% in group B (mean follow-up, 6 +/- 3 months; <em>P</em> = .04). There was only 1 procedure-related death caused by cerebral bleeding and herniation in group A. The freedom-from-reintervention rate at 6 months was 100% in group A (mean follow-up, 12 +/- 11.5 months) and 90% in group B (mean follow-up, 6 +/- 3.9 months; <em>P</em> = .07). No branch occlusions were observed in group A, whereas a branch occlusion occurred in 3 patients in group B (in all cases the bridging endograft for the renal artery). In 2 patients, the possible reason for branch occlusion was a thrombophilic disorder, whereas in 1 patient, the reason remains unknown. Paraplegia was observed in 1 patient in each group (group A: 4%; group B: 5%; <em>P</em> = .51) and persistent paraparesis in 2 patients in group A (8%) and in 1 patient (5%) in group B (<em>P</em> = .94).</td>

### Reference Study Type Patients/Events Study Objective (Purpose of Study) Study Results

**Review/Other-Dx**

**N/A**

To provide current practical information to radiologists, other physicians, and medical practitioners implementing policies for imaging pregnant and potentially pregnant patients.

No results stated in abstract.

4

**Review/Other-Dx**

1,883 cardiological and surgical patients

To present the results of the hybrid operating room concept encompassing simultaneous hemodynamic control, noninvasive and invasive diagnostics and immediate surgical and/or interventional treatment.

Preoperative angiography was performed in 71 patients, and no angiography related complications were observed during the procedure. A total of 32% (23/71) of these underwent coronary artery bypass graft for newly-diagnosed coronary artery disease in 21% of cases and for coronary malperfusion in 11%. Visceral/peripheral malperfusion syndromes, necessitating primary endovascular intervention, were detected in 23% (16/71). Ascending aorta replacement was performed in 100% (124/124) of patients, arch replacement in 88% (109/124) and descending aorta repair in 35% (44/124). 5 postoperative endovascular interventions became necessary due to persistent malperfusion. In-hospital mortality was 13% (12/90) in patients who had undergone preoperative invasive diagnostics and 24% (8/34) in patients who had not.

4

**Observational-Dx**

30 patients

To compare the sensitivity of intra-aortic CTA to that of regular spinal digital subtraction angiography for the presurgical location of the Adamkiewicz artery.

The Adamkiewicz artery was visualized by the intra-aortic CTA in 27/30 cases (90%); in 26/31 (84%) cases, the continuity with the aorta was satisfactorily seen. Interrater agreement was good for the visualization of the Adamkiewicz artery and its feeder(s): 0.625 and 0.87, respectively. In 75% of the cases for which the Adamkiewicz artery was visualized, the selective catheterization confirmed the results of the intra-aortic CTA. In the remaining 25% of the cases, the selective catheterization could not be performed due to marked vessels' tortuosity or ostium stenosis.

<td>Observational-Tx</td>
<td>343 patients</td>
<td>To assess the adequacy of a limited cardiac evaluation before TEVAR, including assessment of cardiac symptoms, resting electrocardiography, and transthoracic echocardiography, as well as to estimate the incidence of perioperative cardiac events in patients undergoing TEVAR.</td>
<td>No preoperative cardiac workup was performed for 28 patients (7.4%); 127 patients (33.4%) had resting electrocardiography only, 208 patients (54.7%) had resting echocardiography, 12 patients (3.2%) underwent stress testing, and 5 patients (1.3%) had coronary angiography. Patients undergoing stress testing or coronary angiography were older and had a higher incidence of known coronary artery disease (<em>P</em>&lt;.01) and prior myocardial infarction (<em>P</em>=.01). Complex hybrid aortic repairs and TEVAR for aneurysmal disease were more likely to have an extensive workup, whereas nonelective procedures more commonly had no workup. A total of 9 patients (2.4%) experienced a perioperative cardiac event (myocardial infarction or cardiac arrest), with no significant difference noted among all groups (<em>P</em>=.45), suggesting that the extent of cardiac workup was appropriate. The incidence of 30-day/in-hospital mortality (5.5%) and cardiac-specific mortality (0.8%) was similar among all groups.</td>

<td>68. Bensley RP, Hurks R, Huang Z, et al. Ultrasound-guided percutaneous endovascular aneurysm repair success is predicted by access vessel diameter. <em>J Vasc Surg.</em> 2012;55(6):1554-1561.</td>
<td>Observational-Tx</td>
<td>168 patients</td>
<td>To describe our experience with percutaneous endovascular aneurysm repair and to compare our outcomes with the published literature.</td>
<td>168 patients (296 arteries) had percutaneous access endovascular aneurysm repair whereas 131 patients (226 arteries) had femoral cutdown access endovascular aneurysm repair. US scan-guided access was introduced in 2007. Percutaneous endovascular aneurysm repair increased from zero cases in 2005 to 92.3% of all elective cases in 2010. The success rate with percutaneous access was 96%. Failures requiring open surgical repair of the artery included 7 for hemorrhage and 6 for flow-limiting stenosis or occlusion of the femoral artery. Percutaneous endovascular aneurysm repair had fewer wound complications (0.7% vs 7.4%; <em>P</em>=.001), shorter operative time (153.3 vs 201.5 minutes; <em>P</em>&lt;.001), and larger minimal access vessel diameter (6.7 mm vs 6.1 mm; <em>P</em>&lt;.01). Patients with failed percutaneous access had smaller minimal access vessel diameters when compared to successful percutaneous endovascular aneurysm repair (4.9 mm vs 6.8 mm; <em>P</em>&lt;.001). More failures occurred in small sheaths than large ones (7.4% vs 1.9%; <em>P</em>=.02). Access vessel diameter &lt;5 mm is predictive of percutaneous failure (16.7% of vessels &lt;5 mm failed vs 2.4% of vessels ≥5 mm failed; <em>P</em>&lt;.001; OR, 7.3; 95% CI, 1.58-33.8; <em>P</em>=.01).</td>

<td>70. Kato K, Nishio A, Kato N, Usami H, Fujimaki T, Murohara T. Uptake of 18F-FDG in acute aortic dissection: a determinant of unfavorable outcome. <em>J Nucl Med.</em> 2010;51(5):674-681.</td>
<td>Observational-Dx</td>
<td>28 patients</td>
<td>To investigate the use of FDG-PET/CT to predict short- and midterm outcomes in medically controlled acute aortic dissection patients.</td>
<td>Maximum dissection diameter in the unfavorable group was significantly greater than that in the favorable group (<em>P</em> = 0.0207). On 50-min images, maximal and mean SUV at maximum aortic dissection sites were significantly greater for the unfavorable group than for the favorable group (all <em>P</em>&lt;0.01). A stepwise-forward selection procedure demonstrated that the mean SUV at sites of maximum aortic dissection on 50-min images significantly and independently predicted an unfavorable outcome for acute aortic dissection (<em>P</em> = 0.0171; OR, 7.72; 95% CI, 1.44–41.4; R(2) = 0.2372). A mean SUV &gt;3.029 had significant predictive power, with sensitivity of 75.0%, specificity of 70.0%, a PPV of 50.0%, a NPV of 87.5%, and accuracy of 71.4%. Greater uptake of FDG in acute aortic dissection was significantly associated with an increased risk for rupture and progression. FDG-PET/CT may be used to improve acute aortic dissection patient management, although more studies are still needed to clarify its role in this clinical scenario.</td>

<td>75. Ganapathi AM, Andersen ND, Hanna JM, Gaca JG, McCann RL, Hughes GC. Comparison of attachment site endoleak rates in Dacron versus native aorta landing zones after thoracic endovascular aortic repair. <em>J Vasc Surg</em>. 2014;59(4):921-929.</td>
<td>Observational-Tx</td>
<td>697 landing zones</td>
<td>To compare the rate of type I endoleak occurring in Dacron landing zones vs native aorta landing zones using a large, single-institution TEVAR database that contains a high proportion of complex hybrid reconstructions involving endograft landing zones in segments of previously reconstructed Dacron aorta.</td>
<td>Identified were 697 proximal or distal landing zones (native aorta, 599; Dacron, 79; and endograft, 19). Patients with at least 1 Dacron landing zone had higher rates of hypertension (<em>P</em>&lt;.01), chronic obstructive pulmonary disease (<em>P</em>=.04), and prior aortic surgery (<em>P</em>&lt;.01) and were more likely to have undergone complex hybrid repairs (<em>P</em>&lt;.01). Cumulative type I endoleak rates were equivalent between the 3 types of landing zone (native aorta, 3.7%; Dacron, 2.5%; endograft, 0%; <em>P</em>=.44). Two type I endoleaks occurred with Dacron landing zones in the first tertile of TEVAR experience and with Dacron landing zone lengths of &lt;2.5 cm. Evaluation of endoleak rates by tertile of experience demonstrated decreased type I endoleak rates in Dacron landing zones between the first and second/third tertiles of experience (13.3% vs 0%, <em>P</em>=.03) after a policy of using &gt;4 to 5 cm (twice the device instructions for use) of Dacron overlap was initiated.</td>

<td>83. Murphy EH, Szeto WY, Herdrich BJ, et al. The management of endograft infections following endovascular thoracic and abdominal aneurysm repair. <em>J Vasc Surg.</em> 2013;58(5):1179-1185.</td>
<td>Observational-Tx</td>
<td>18 patients</td>
<td>To examine the results of treatment at a single center for the management of infected aortic endografts.</td>
<td>Overall, 18 patients were treated for infected endografts (thoracic: 6, abdominal: 12). 3 patients were treated between 2000 and 2006, corresponding to a 0.6% institutional incidence of endograft infection (3/473). There were no transfers for infected endografts from outside institutions. From 2006 to 2011, 15 patients underwent treatment. 6 were institutional cases of infections (6/945, 0.6% infection rate), however, there was an increase in transfers (n = 9). Median time to presentation with infection from endograft implant was 90 days, with over one-half (61%) presenting within the first 3 months. Tissue and/or blood cultures were positive in 12/16 growing Escherichia coli (n = 1), group A streptococcus (n = 3), methicillin-resistant Staphylococcus aureus (n = 3), or polymicrobial infections (n = 7). The other 4 patients were culture negative with CT evidence of gas surrounding the endograft and clinical sepsis. 10 patients (abdominal: 8, thoracic: 2) were treated with endograft explantation. The remaining 8 patients were considered too high-risk for explant or refused open surgery and were therefore managed conservatively without explant (abdominal: 4, thoracic: 4). At a mean follow-up of 24.7 months, aneurysm-related mortality was 38.9% (n = 7) and was higher for patients presenting with aortoenteric or aortobronchial fistulas (n = 6/10, 60%) (P=.04) and for thoracic stent infections (n = 5/6; 83%) (P=.03). The only survivor of a thoracic infection was managed surgically. Overall survival for patients with abdominal endografts (n = 12) was similar between the 8 patients managed surgically (n = 6/8; 75%) and the 4 selected for medical management (n = 4/4; 100%) (P=.39). All survivors remain on long-term suppressive antibiotics. 2 additional patients died of unrelated causes during follow-up.</td>

<td>84. Zoli S, Trabattoni P, Dainese L, et al. Cumulative radiation exposure during thoracic endovascular aneurysm repair and subsequent follow-up. <em>Eur J Cardiothorac Surg.</em> 2012;42(2):254-259; discussion 259-260.</td>
<td>Observational-Tx</td>
<td>48 patients</td>
<td>To investigate cumulative radiation exposure of patients undergoing TEVAR—including the preoperative workup, the procedure and recurrent follow-up CT imaging</td>
<td>The average screening time was 15.7 +/- 11.4 min, with an radiation exposure of 11.3 +/- 9 mSv. Obese patients had significantly higher radiation exposure during TEVAR (Pearson’s coefficient = 0.388, P=0.019). The radiation exposure dropped from 14.9 +/- 9.4 mSv to 8.6 +/- 7.9 mSv (P=0.033) after a hybrid suite was established. Our institutional TEVAR protocol involves 1 preoperative thoracoabdominal CT scan and 3 follow-up thoracic CT scans for the first year, with a yearly evaluation thereafter. The life expectancy of an age- and sex-matched population was 17 years. A patient adhering to our surveillance protocol would be subjected to an overall exposure of 89 mSv at 1 year and 161 mSv at 5 years, with a projected lifetime radiation exposure &gt;350 mSv.</td>

<td>Observational-Dx</td>
<td>11 patients</td>
<td>To compare contrast-enhanced MRA and multislice CTA in the follow-up of thoracic stent-graft placement.</td>
<td>The contrast-enhanced MRA and multislice CTA were performed following nitinol stent-graft treatment due to thoracic aneurysm ($n=4$), intramural bleeding ($n=2$) and type-B aortic dissection ($n=5$). Corresponding evaluation of arterial-phase imaging characteristics focused on the stent-graft morphology and leakage assessment. Stent-graft and aneurysm extensions were comparable between both techniques. Complete exclusion (aneurysm, $n=4$; dissection, $n=2$) was assessed with high confidence with contrast-enhanced MRA and multislice CTA. Incomplete exclusion (intramural bleeding, $n=2$; dissection, $n=3$) was assigned to lower confidence scores on contrast-enhanced MRA compared with multislice CTA. On contrast-enhanced MRA the stent-graft lumen demonstrated an inhomogeneous signal; the stent struts could not be assessed.</td>

<td>Review/Other-Dx</td>
<td>35 articles</td>
<td>To review and evaluate the safety of color-duplex US as compared with CT, based on the current literature, for post-endovascular abdominal aortic aneurysm surveillance.</td>
<td>There was a substantial heterogeneity among the studies due to the following reasons: 1. The wide range of the number of patients enrolled in each study (20–561). 2. Variation in CT protocol (CT or CTA, arterial phase, biphasic or triple phase). 3. The interobserver reliability for the US imaging, which was not defined with the exception of 2 studies: (a) Zannetti et al in 2000, evaluated the interobserver agreement in endoleak detection (k analysis value ¼ 1) and in a type of endoleak (k ¼ 0. 7) in 50 random duplex examinations. (b) Lezzi et al in 2009, estimated that the interobserver agreement in all reading sessions of enhanced color-duplex US for endoleak detection was high (k analysis value 0.89). In 6 studies all the US examinations were conducted by 1 single vascular sonographer. Color-duplex US or enhanced color-duplex US were performed by experienced vascular technologists in 18 trials. There is no information reported about the color-duplex US/enhanced color-duplex US operators for the rest 11 studies. Moreover, differences in US equipment quality, particularly in the earlier studies with less advanced US instruments, have not been evaluated.</td>

<td>91. Nakai M, Sato H, Sato M, et al. Utility of (99m)Tc-human serum albumin diethylenetriamine pentaacetic acid SPECT for evaluating endoleak after endovascular abdominal aortic aneurysm repair. AJR Am J Roentgenol. 2015;204(1):189-196.</td>
<td>Observational-Dx</td>
<td>15 patients</td>
<td>To assess the utility of (99m)Tc-HSAD SPECT in the detection of endoleaks after endovascular abdominal aortic aneurysm repair.</td>
<td>Endoleaks were interpreted as perigraft radioisotope accumulation in 12 patients (80.0%) on (99m)Tc-HSAD SPECT images, in 13 patients (86.7%) on three-phase CT images, and in 15 patients (100%) on CT during aortography. The mean endoleak volume visualized with (99m)Tc-HSAD SPECT was 8.37 cm³ (range, 5.2-15.1 cm³), and the volume not visualized was 3.47 cm³ (2.5-4.6 cm³), a statistically significant difference (P=0.019). In 2 patients, (99m)Tc-HSAD SPECT depicted endoleaks evident at delayed phase CT during aortography but not at three-phase CT, suggesting they were slow-filling endoleaks. Accumulation of (99m)Tc-HSAD corresponding to endoleaks disappeared after embolization, but CT evaluation of embolization was impeded by artifacts of NBCA-Lipiodol and metallic coils.</td>

## Evidence Table Key

### Study Quality Category Definitions

- **Category 1**  The study is well-designed and accounts for common biases.
- **Category 2**  The study is moderately well-designed and accounts for most common biases.
- **Category 3**  There are important study design limitations.
- **Category 4**  The study is not useful as primary evidence. The article may not be a clinical study or the study design is invalid, or conclusions are based on expert consensus. For example:
  a) the study does not meet the criteria for or is not a hypothesis-based clinical study (e.g., a book chapter or case report or case series description);
  b) the study may synthesize and draw conclusions about several studies such as a literature review article or book chapter but is not primary evidence;
  c) the study is an expert opinion or consensus document.
- **M** = Meta-analysis

### Abbreviations Key

- **AAS** = Acute aortic syndromes
- **BAV** = Bicuspid aortic valve
- **CI** = Confidence interval
- **CT** = Computed tomography
- **CTA** = Computed tomographic angiography
- **FDG-PET** = Fluorine-18-2-fluoro-2-deoxy-D-glucose-positron emission tomography
- **IMH** = Intramural hematoma
- **MRA** = Magnetic resonance angiography
- **MRI** = Magnetic resonance imaging
- **NPV** = Negative predictive value
- **OR** = Odds ratio
- **PPV** = Positive predictive value
- **SPECT** = Single-photon-emission computed tomography
- **SUV** = Standardized uptake value
- **TEVAR** = Thoracic endovascular aortic repair
- **US** = Ultrasound
