<td>4. Heidenreich PA, Albert NM, Allen LA, et al. Forecasting the impact of heart failure in the United States: a policy statement from the American Heart Association. Circ Heart Fail. 2013;6(3):606-619.</td>
<td>Review/Ot her-Dx</td>
<td>N/A</td>
<td>To update and expand on prior work and provide an in-depth look at how the changing demographics in the United States will impact the prevalence and cost of care for Heart failure (HF) for different US populations.</td>
<td>We estimated future costs of HF by adapting a methodology developed by the American Heart Association to project the epidemiology and future costs of HF from 2012 to 2030 without double counting the costs attributed to comorbid conditions. The model assumes that HF prevalence will remain constant by age, sex, and race/ethnicity and that rising costs and technological innovation will continue at the same rate. By 2030, &gt;8 million people in the United States (1 in every 33) will have HF. Between 2012 and 2030, real (2010$) total direct medical costs of HF are projected to increase from $21 billion to $53 billion. Total costs, including indirect costs for HF, are estimated to increase from $31 billion in 2012 to $70 billion in 2030. If one assumes all costs of cardiac care for HF patients are attributable to HF (no cost attribution to comorbid conditions), the 2030 projected cost estimates of treating patients with HF will be 3-fold higher ($160 billion in direct costs).</td>

<td>5.</td>
<td>Observatio nal-Dx</td>
<td>3757 men &amp; 4472 women</td>
<td>To understand the Lifetime risk for developing congestive heart failure.</td>
<td>Among Framingham Heart Study subjects who were free of CHF at baseline, we determined the lifetime risk for developing overt CHF at selected index ages. We followed 3757 men and 4472 women from 1971 to 1996 for 124 262 person-years; 583 subjects developed CHF and 2002 died without prior CHF. At age 40 years, the lifetime risk for CHF was 21.0% (95% CI 18.7% to 23.2%) for men and 20.3% (95% CI 18.2% to 22.5%) for women. Remaining lifetime risk did not change with advancing index age because of rapidly increasing CHF incidence rates. At age 80 years, the lifetime risk was 20.2% (95% CI 16.1% to 24.2%) for men and 19.3% (95% CI 16.5% to 22.2%) for women. Lifetime risk for CHF doubled for subjects with blood pressure ≥160/100 versus &lt;140/90 mm Hg. In a secondary analysis, we only considered those who developed CHF without an antecedent myocardial infarction; at age 40 years, the lifetime risk for CHF was 11.4% (95% CI 9.6% to 13.2%) for men and 15.4% (95% CI 13.5% to 17.3%) for women.</td>

<td>6. Merlo M, Pivetta A, Pinamonti B, et al. Long-term prognostic impact of therapeutic strategies in patients with idiopathic dilated cardiomyopathy: changing mortality over the last 30 years. Eur J Heart Fail. 2014;16(3):317-324.</td>
<td>Observational-Dx</td>
<td>To analyse the long-term prognostic impact of evidence-based integrated therapeutic strategies in patients with idiopathic dilated cardiomyopathy (IDCM).</td>
<td>From 1978 to 2007, 853 IDCM patients (45 +/- 15 years, 72% males) were enrolled and classified as follows: Group 1, 110 patients (12.8%) enrolled during 1978-1987; Group 2, 376 patients (44.1%) enrolled during 1988-1997; Group 3, 367 patients (43.1%) enrolled during 1998-2007. ACE-inhibitors/angiotensin receptor blockers were administered in 34%, 93%, and 93% (P &lt;0.001), and beta-blockers in 11%, 82%, and 86% (P &lt;0.001) in Groups 1, 2, and 3, respectively; implantable cardioverter-defibrillator (ICD) were implanted in 2%, 14%, and 13% (P = 0.005); mean time to device implantation was lower in Group 3. At 8 years, heart transplant (HTx)-free survival rates were 55%, 71%, and 87% in Groups 1, 2, and 3, respectively (P &lt;0.001). Similar progressive improvement was found for pump-failure death (DHF)/HTx, while survival free from sudden death (SD) was significantly improved only in Group 3. Multivariable models considering competing risk indicated early diagnosis (i.e. a baseline less advanced disease stage) and tailored medical therapy (HR 0.44, CI 95% 0.19-0.98) as independent protectors against DHF/HTx. Concerning SD, lower left ventricular ejection fraction emerged as a predictor, while ICD was the only therapy with a protective role (HR 0.08, CI 95% 0.01-0.61). Treatment with digitalis emerged as a predictor of both DHF/HTx and SD.</td>

**Study Type**: Review/Ot her-Dx  
**Reference**: N/A  
**Study Objective** (Purpose of Study): To test the hypothesis that the incidence of heart failure has declined and survival after heart failure diagnosis has improved over time but that secular trends have diverged by sex.  
**Study Results**: The incidence of heart failure was higher among men (378/100 000 persons; 95% confidence interval [CI], 361-395 for men; 289/100 000 persons; 95% CI, 277-300 for women) and did not change over time among men or women. After a mean follow-up of 4.2 years (range, 0-23.8 years), 3347 deaths occurred, including 1930 among women and 1417 among men. Survival after heart failure diagnosis was worse among men than women (relative risk, 1.33; 95% CI, 1.24-1.43) but overall improved over time (5-year age-adjusted survival, 43% in 1979-1984 vs 52% in 1996-2000, P<.001). However, men and younger persons experienced larger survival gains, contrasting with less or no improvement for women and elderly persons.

<td>Observatio nal-Dx</td>
<td>216 chest radiographs of 61 patients</td>
<td>To determine, as objectively and rigorously as possible, the validity of the chest radiograph in deciding what type of pulmonary edema is present, in order to provide a rational pathophysiologic basis for the treatment of that particular type of edema.</td>
<td>Three principal and seven ancillary features have been identified, all of which are statistically significant and permit the cause of the edema to be determined correctly in a high percentage of cases. The three principal features are distribution of pulmonary flow, distribution of pulmonary edema, and the width of the vascular pedicle. The ancillary features are pulmonary blood volume, peribronchial cuffing, septal lines, pleural effusions, air bronchograms, lung volume, and cardiac size. Differing constellations of these features occur, each of which is characteristic of a specific type of edema. Overall accuracy of diagnosis in this study ranged from 86% to 89%. The highest accuracy was obtained in distinguishing capillary permeability edema from all other varieties (91%), and the lowest in distinguishing chronic cardiac failure from renal failure (81%).</td>

<td>Review/Other-Dx</td>
<td>N/A</td>
<td>To reinforce the information on the use of nuclear cardiology techniques for the assessment of heart failure and associated myocardial disease.</td>
<td>Heart failure is increasing worldwide at epidemic proportions, resulting in considerable disability, mortality, and increase in healthcare costs. Gated myocardial perfusion single photon emission computed tomography or PET imaging is the most prominent imaging modality capable of providing information on global and regional ventricular function, the presence of intraventricular synchronism, myocardial perfusion, and viability on the same test. In addition, I-mIBG scintigraphy is the only imaging technique approved by various regulatory agencies able to provide information regarding the adrenergic function of the heart. Therefore, both myocardial perfusion and adrenergic imaging are useful tools in the workup and management of heart failure patients.</td>

<td>Review/Ot her-Dx</td>
<td>N/A</td>
<td>To provide a report to the public of data from the Cath percutaneous coronary intervention (PCI) Registry of the National Cardiovascular Data Registry.</td>
<td>Some notable findings include, for example, that on-site cardiac surgery was not available in 83% of facilities performing fewer than 200 PCIs annually, with these facilities representing 32.6% of the facilities reporting, but performing only 12.4% of the PCIs in this data sample. Patients 65 years of age or older represented 38.7% of those undergoing PCI, with 12.3% being 80 years of age or older. Almost 80% of PCI patients were overweight (body mass index &gt;/=25 kg/m(2)). 80% had dyslipidemia, and 27.6% were current or recent smokers. Among patients undergoing elective PCI, 52% underwent a stress study before the procedure, with stress myocardial perfusion being used most frequently. Calcium scores and coronary computed tomography angiography were used very infrequently (&lt;3%) before diagnostic or PCI procedures. Radial artery access was used in 8.3% of diagnostic and 6.9% of PCI procedures. Primary PCI was performed with a median door-to-balloon time of 64.5 min for nontransfer patients and 121 min for transfer patients. In-hospital risk-adjusted mortality in ST-segment elevation myocardial infarction patients was 5.2% in this sample.</td>

### Reference

#### Study Type
- Observational-Dx

#### Patients/Events
- 55

#### Study Objective
- To evaluate the ability of emergency physicians to recognize CHF on chest X-ray and the effect of level of training and confidence upon accuracy of interpretation.

#### Study Results
- Physicians correctly identified the CHF chest X-rays 79% of the time (sensitivity 59%, specificity 96%; positive likelihood ratio 14.6, negative likelihood ratio 0.43). Accuracy ranged from a low of 78% among first-year residents to a high of 85% among attendings, and from 73% (confidence rating of 3/5) to 91% (confidence rating of 5/5). Increasing confidence was significantly correlated with accuracy across the spectrum (p < 0.001). An accuracy of 95% among radiologists suggests that a negative X-ray does not rule out CHF. High specificity (96%) and low sensitivity (59%) suggest that emergency physicians are excellent at identifying CHF on X-ray when present, but under-call it frequently. Sensitivity may be much higher in real life given clinical correlation. Both increased level of training and higher confidence significantly improved accuracy.

#### Study Quality

- Observational-Dx

#### Patients/Events
- 624 patients

#### Study Objective
- To evaluate in acute myocardial infarction (AMI) patients the ability of proposed radiological score (RS), which is the sum of selected radiological signs of congestion, to reflect correctly lung fluid content (LFC), as assessed with repeat physical examinations and lung impedance (LI) measurements.

#### Study Results
- 624 acute myocardial infarction (AMI) patients without acute heart failure (AHF) at baseline were monitored (94 +/- 42 h). 476 patients (76%) with baseline RS of 0.3 +/- 0.5 did not develop AHF. Overt AHF developed in 148 patients (24%) during monitoring; baseline RS (0.6 +/- 0.8) reached 5.4 +/- 0.7, 7.0 +/- 0.8, and 9.8 +/- 0.5 at the stages of mild, moderate, and severe alveolar edema, respectively. AHF resolved with treatment. RS decreased to 1.5 +/- 1.3 (P < 0.01) and correlated with physical examination (r = 0.6, P < 0.01) and LI (r = -0.9, P < 0.01).

<td>39. Collins SP, Lindsell CJ, Yealy DM, et al. A comparison of criterion standard methods to diagnose acute heart failure. Congest Heart Fail. 2012;18(5):262-271.</td>
<td>Observatio nal-Dx</td>
<td>483 patients</td>
<td>To compare and contrast the clinical criterion standards currently used in a cohort of emergency department (ED) patients to diagnose acute heart failure syndromes (AHFS).</td>
<td>Across all criterion standards, patients with AHFS were more likely to have a history of AHFS, congestion on physical examination and chest radiography, and elevated natriuretic peptide levels than those without AHFS. The standards agreed well (cardiology review vs hospital discharge diagnosis, kappa=0.74; cardiology review vs ED diagnosis, kappa=0.66; ED diagnosis vs hospital discharge diagnosis kappa=0.59). Each method had similar sensitivity but differing specificities. Different criterion standards identify different patients from among those being evaluated for AHFS.</td>

<td>40. Kelder JC, Cramer MJ, van Wijngaarden J, et al. The diagnostic value of physical examination and additional testing in primary care patients with suspected heart failure. Circulation. 2011;124(25):2865-2873.</td>
<td>Observational-Dx</td>
<td>721 patients</td>
<td>To determine the diagnostic value of history, physical examination, and subsequent additional testing including B-type natriuretic peptide (BNP) measurements to efficiently and accurately establish a diagnosis of new-onset heart failure in the domain of outpatients presenting with nonacute symptoms.</td>
<td>His is a cross-sectional diagnostic accuracy study with external validation. Seven hundred twenty-one consecutive patients suspected of new-onset heart failure underwent standardized diagnostic work-up including chest x-ray, spirometry, electrocardiography (ECG), N-terminal pro-B-type natriuretic peptide (NT-proBNP) measurement, and echocardiography in specially equipped outpatient diagnostic heart failure clinics. The presence of heart failure was determined by an outcome panel using the initial clinical data and 6-month follow-up data, blinded to biomarker data. Of the 721 patients, 207 (28.7%) had heart failure. The combination of 3 items from history (age, coronary artery disease, and loop diuretic use) plus 6 from physical examination (pulse rate and regularity, displaced apex beat, rales, heart murmur, and increased jugular vein pressure) showed independent diagnostic value (c-statistic 0.83). NT-proBNP was the most powerful supplementary diagnostic test, increasing the c-statistic to 0.86 and resulting in net reclassification improvement of 69% (P&lt;0.0001). A simplified diagnostic rule was applied to 2 external validation datasets, resulting in c-statistics of 0.95 and 0.88, confirming the results.</td>

**Study Type**: Experimental-Dx

**Patients/Events**: 226 patients

**Study Objective (Purpose of Study)**: To evaluate the effects of aldosterone blockade, with eplerenone, on left ventricular (LV) remodeling and markers of collagen turnover in patients with LV systolic dysfunction and chronic mild-to-moderate heart failure (HF).

**Study Results**: In a multicenter, randomized, double-blind, placebo-controlled study in patients with mild-to-moderate HF and LV systolic dysfunction, patients with New York Heart Association class II/III HF and LV ejection fraction (EF) \( \leq 35\% \) were randomly assigned to receive eplerenone 50 mg/d versus placebo in addition to contemporary background therapy. Quantitative radionuclide ventriculograms to assess LV volumes and ejection fraction were performed at baseline and again after 9 months of double-blind treatment and were analyzed in a central core laboratory, blinded to treatment. The primary efficacy analysis was the between-group comparison of the change in LV end-diastolic volume index. Secondary analyses examined changes in LV end-systolic volume index and ejection fraction as well as markers of collagen turnover. Of the total 226 patients enrolled, 117 were randomly assigned to receive eplerenone and 109 to receive placebo. There was high use of contemporary background therapy at baseline, with >90% use of angiotensin-converting enzyme inhibitors and/or angiotensin receptor blockers and >90% use of beta-blockers. Over 36 weeks of treatment, there was no apparent between-group difference in the changes in end-diastolic volume index or end-systolic volume index. There was a reduction in the collagen turnover marker procollagen type 1 N-terminal propeptide and plasma B-type natriuretic peptide in the eplerenone group compared with placebo (\( P=0.01 \) and \( P=0.04 \), respectively). There was no change in symptom status or quality-of-life measures.

### Study Objective

To evaluate the ability of late gadolinium enhancement (LGE) using cardiovascular magnetic resonance (CMR) to identify acute new-onset heart failure (HF) with left ventricular systolic dysfunction (LVSD), whether or not in relation to underlying coronary artery disease (CAD), in patients with no clinical evidence of associated ischaemic cardiomyopathy.

### Study Results

Hundred consecutive patients admitted with acute new-onset decompensated HF and EF <40%, with no clinical or electrocardiographic data suggestive of CAD. The patients were classified according to the presence or absence of significant CAD (stenosis ≥70% in at least one major vessel). Twenty-one patients (21%) had significant CAD. Seventy-nine (79%) had no lesions. Eighteen of the 21 patients (85%) with CAD had subendocardial/transmural LGE. In the diagnosis of CAD, LGE has a sensitivity of 85.7% (95% CI, 80-91) and specificity of 92.4% (95% CI, 87-96), respectively, with a negative predictive value of 96% (95% CI, 90-99). It has an area under the receiver operating characteristic curve of 0.906 (95% CI, 0.814-0.998).

<td>Review/Ot her-Dx</td>
<td>110,621 patients</td>
<td>To analyze data from 275 hospitals in Get With the Guidelines-Heart Failure from January 2005 to October 2010.</td>
<td>Among 110,621 patients, 50% (55,083) had HF-reduced ejection fraction (EF), 14% (15,184) had HF-borderline EF, and 36% (40,354) had HF-preserved EF. From 2005 to 2010, the proportion of hospitalizations for HF-preserved EF increased from 33% to 39% (P&lt;0.0001). In multivariable analyses, use of angiotensin-converting enzyme inhibitors/angiotensin receptor blockers at discharge decreased in all EF groups, and beta-blocker use increased. Patients with HF-preserved EF less frequently achieved blood pressure control (adjusted odds ratio, 0.44 versus HF-reduced EF; P&lt;0.001) and were more likely discharged to skilled nursing (adjusted odds ratio, 1.16 versus HF-reduced EF; P&lt;0.001). In-hospital mortality for HF-preserved EF decreased from 3.32% in 2005 to 2.35% in 2010 (adjusted odds ratio, 0.89 per year; P=0.01) but was stable for patients with HF-reduced EF (3.03%-2.83%; adjusted odds ratio, 0.93 per year; P=0.10).</td>

Revised 2018

Page 34

**Study Type**: Observational-Dx  
**Patients/Events**: 141 patients  
**Study Objective (Purpose of Study)**: To assess the power of left atrial (LA) parameters for predicting left ventricular (LV) filling pressure and adverse events in acute heart failure (HF) with severe LV dysfunction, either sinus rhythm or atrial fibrillation (AF)  

**Study Results**: Echocardiography was performed in 141 patients with acute decompensated congestive HF and LV ejection fraction <35%, including 42 with permanent AF. The LA expansion index was calculated as (Volmax - Volmin) x 100%/Volmin, where Volmax was defined as maximal and Volmin as minimal LA volume. Of 141 patients, invasive LV filling pressures within 12 hours of LA expansion index measurement were available in 109. The end points were 3-year frequencies of HF hospitalization and all-cause mortality. Over a median follow-up of 3.1 years, 74 participants (52.5%) reached the end points (sinus vs AF group: 48.5% vs 61.9%, respectively; P = .047). Multivariate analysis revealed that adverse events of both groups were only independently associated with age and LA expansion index. Rates of adverse events were proportional to LA expansion index. There was a good logarithmic relationship between LA expansion index and LV filling pressure, regardless of presence or absence of AF.

<td>Observational-Dx</td>
<td>180 patients</td>
<td>To evaluate the effect of this dysfunction on prognosis in patients with newly-diagnosed systolic heart failure (HF).</td>
<td>We enrolled 180 consecutive patients with newly diagnosed systolic HF (ischemic or dilated cardiomyopathy). Echocardiographic evaluation was performed to assess biventricular function. Pulse-wave tissue Doppler imaging (TDI) readings were obtained from the lateral tricuspid annulus and the peak systolic annular velocity (Stv) was recorded. Patients were followed for a 2-year period and events (death or HF hospitalization) were recorded. During the follow-up, 79 patients (44%) had an adverse event. An inverse relationship was observed between the height of Stv and the probability of an event (odds ratio (OR) 0.716, 95% confidence interval (CI) 0.583-0.880, P=0.001), after controlling for potential confounders. Furthermore, creatinine clearance (CrCl) was inversely associated with the outcome: a 1-unit increase in CrCl was associated with a 0.98-times lower likelihood of having an event. When the analysis was stratified by CrCl &lt; 60 ml/min or &gt;/= 60 ml/min, Stv predicted adverse events in both groups (CrCl &lt; 60 ml/min: OR 0.62, 95%CI 0.39-0.98, P = 0.04; CrCl &gt;/= 60 ml/min: OR 0.78, 95%CI 0.61-1.01, P=0.06).</td>

<td>Review/Ot her-Dx</td>
<td>1527 subjects</td>
<td>To assess the prevalence of unrecognized heart failure in elderly patients presenting to primary care with shortness of breath on exertion.</td>
<td>This was a cross-sectional selective screening study. Patients aged 65 years or over presenting to primary care with shortness of breath on exertion in the previous 12 months were eligible when not known to have an established, echocardiographic confirmed diagnosis of heart failure. All participants underwent history taking, physical examination, electrocardiography, and a blood test of N-terminal pro B-type natriuretic peptide (NTproBNP). Only those with an abnormal electrocardiogram or NTproBNP level exceeding the exclusionary cut-point for non-acute onset heart failure (&gt;15 pmol/L (approximately 125 pg/mL) underwent open-access echocardiography. An expert panel established presence or absence of heart failure according to the criteria of the European Society of Cardiology heart failure guidelines. The mean age of the 585 participants was 74.1 (SD 6.3) years, and 54.5% were female. In total, 92 (15.7%, 95% CI 12.9-19.0) participants had heart failure: 17 (2.9%, 95% CI 1.8-4.7) had heart failure with a reduced ejection fraction (&lt;45%), 70 (12.0%, 95% CI 9.5-14.9) had heart failure with preserved ejection fraction, and five (0.9%, 95% CI 0.3-2.1) had isolated right-sided heart failure.</td>

Diagnosis of heart failure with preserved ejection fraction: which parameters and diagnostic strategies are more valuable? Eur J Heart Fail. 2011;13(7):737-745.

**Study Type:** Observational-Dx

**Patients/Events:** 236 patients

**Study Objective (Purpose of Study):** To evaluate the present main diagnostic criteria and to discover which parameters and strategies are more valuable.

**Study Results:** Echocardiographic data and plasma N-terminal pro-brain natriuretic peptide levels were assessed in a derivation cohort (n=236) and a validation cohort (n=98). Both cohorts included normal controls, patients with hypertensive heart disease without heart failure and patients with heart failure with preserved ejection fraction (HFP EF). In the derivation cohort, the ratio of early mitral inflow velocity to tissue Doppler velocity at lateral mitral annulus (lateral E/e'≥12), left atrial volume index (LAVI≥34 mL/m²), and the difference between duration of reversed pulmonary vein atrial systole flow and duration of mitral A wave flow (Ard-Ad>30 ms) had the greatest diagnostic value among all the single parameters. A brief strategy that consisted of either: (i) lateral E/e'≥12; or (ii) 12>lateral E/e'>8, with either LAVI≥34 mL/m² or Ard-Ad>30 ms, provided good diagnostic accuracy for identifying diastolic dysfunction in HFP EF, with a sensitivity of 77% and specificity of 81%. These observations were confirmed in the validation cohort.

**Study Quality:** 3

<td>Morris DA, Boldt LH, Eichstadt H, Ozcelik C, Haverkamp W. Myocardial systolic and diastolic performance derived by 2-dimensional speckle tracking echocardiography in heart failure with normal left ventricular ejection fraction. Circ Heart Fail. 2012;5(5):610-620.</td>
<td>Observational-Dx</td>
<td>450 patients</td>
<td>To investigate the myocardial systolic and diastolic performance of the left ventricle (LV) in patients with heart failure with normal LV ejection fraction (HFNEF) through novel LV myocardial indices, which assess the systolic and diastolic function of the whole myocardium of the LV.</td>
<td>LV myocardial systolic and diastolic performance were assessed as the average value of peak systolic strain and peak early-diastolic strain rate, respectively, in longitudinal, circumferential, and radial directions from all LV segments using 2-dimensional speckle-tracking echocardiography. We studied patients with HFNEF and a control group consisting of asymptomatic subjects with LV diastolic dysfunction of similar age, sex, and LV ejection fraction. A total of 322 patients were included (92 with HFNEF and 230 with asymptomatic LV diastolic dysfunction). Myocardial systolic and diastolic LV performance were significantly lower in HFNEF (20.13+/-.02% and 1.14+/-.27 s(-1)) than in patients with asymptomatic LV diastolic dysfunction (25.33+/-.06% and 1.37+/-.33 s(-1), respectively; all P&lt;0.0001). In addition, patients with HFNEF with low systolic and diastolic LV myocardial performance had significantly higher LV filling pressures (17.1+/-.6.6 and 17.6+/-.6.3 versus 12.0+/-.5.1 and 11.7+/-.4.7, respectively; all P&lt;0.001) and lower cardiac output (4.8+/-.1.0 L/min and 4.9+/-.1.1 L/min versus 5.7+/-.1.2 L/min and 5.8+/-.1.1 L/min, respectively; all P&lt;0.001) than patients with normal LV myocardial performance. In relation to these findings, the symptomatic status (ie, New York Heart Association functional class) was significantly altered in those patients with low systolic and diastolic LV myocardial performance.</td>
<td>2</td>
</tr>
</tbody>
</table>
To test the hypothesis that left ventricular (LV) mechanical dyssynchrony deteriorates the longitudinal systolic and diastolic function of the left ventricle (LV) in patients with heart failure with a normal LV ejection fraction (HFNEF).

In patients with HFNEF and in a control group consisting of asymptomatic patients with LV diastolic dysfunction (LVDD), matched by age, gender, and LV ejection fraction, we assessed the global longitudinal systolic (global strain), diastolic (global early-diastolic strain rate (SRe)), and synchronous (standard deviation of time-to-peak systolic strain) function of the LV by two-dimensional speckle-tracking echocardiography using a 18-segment LV model. A total of 325 patients were included (85 with HFNEF and 240 with asymptomatic LVDD). Patients with HFNEF had a significant impairment of the longitudinal systolic and diastolic function of the LV as compared with the control group. Concerning the pathophysiological mechanisms linked to these findings, we found that HFNEF patients with asynchronous LV contractions had significantly more impaired longitudinal systolic and diastolic LV function (global strain -14.76 +/- 3.44%, global SRe 0.79 +/- 0.24 s(-1)) than patients without asynchronous LV contractions (global strain -18.57 +/- 3.10%, global SRe 1.06 +/- 0.32 s(-1); all P < 0.0001). Accordingly, in HFNEF patients with LV mechanical dyssynchrony the rates of LV longitudinal systolic and diastolic dysfunction were 64 and 70%, respectively, whereas these rates were significantly lower (19.5 and 41.3%), respectively, in patients without asynchronous LV contractions. In addition, HFNEF patients with LV mechanical dyssynchrony presented higher LV filling pressures and worse NYHA functional class than those with normal LV contractions.
### Study Objective (Purpose of Study)

To hypothesize that in patients with heart failure with normal left ventricular (LV) ejection fraction (HFNEF), the same fibrotic processes that affect the subendocardial layer of the LV could also alter the subendocardial fibers of the right ventricle (RV).

### Study Results

A total of 565 patients were included (201 with HFNEF and 364 with asymptomatic LVDD). RV longitudinal diastolic (RV global longitudinal early-diastolic strain rate [RV-SRe]) and systolic (RV global longitudinal systolic strain [RV-Strain]) function were significantly more impaired in patients with HFNEF than in patients with asymptomatic LVDD (HFNEF: RV-Strain -14.41% +/- 3.80% and RV-SRe 0.86 +/- 0.33 s(-1); asymptomatic LVDD: RV-Strain -16.90% +/- 4.28% and RV-SRe 1.02 +/- 0.34 s(-1); all P < .0001). On multiple regression analysis, LV global longitudinal systolic strain was the most important independent predictor of RV longitudinal systolic and diastolic function, in contrast with pulmonary arterial systolic pressure, which was weakly related to these functions. Furthermore, in patients with HFNEF the subendocardial function of both the LV and RV were significantly impaired in similar proportions. In that regard, in patients with HFNEF the prevalences of RV longitudinal systolic and diastolic dysfunction were 75% and 48%, whereas the rates of LV longitudinal systolic and diastolic dysfunction were 80% and 60%, respectively. In addition, patients with both systolic and diastolic longitudinal dysfunction of the RV presented worse New York Heart Association functional class.

<td>76. Morris DA, Gailani M, Vaz Perez A, et al. Left atrial systolic and diastolic dysfunction in heart failure with normal left ventricular ejection fraction. J Am Soc Echocardiogr. 2011;24(6):651-662.</td>
<td>Observatio-nal-Dx</td>
<td>420 patients</td>
<td>To hypothesize that in patients with heart failure with normal left ventricular (LV) ejection fraction (HFNEF), the same fibrotic processes that affect the subendocardial layer of the left ventricle could also alter the subendocardial fibers of the left atrium.</td>
<td>A total of 420 patients were included (119 with HFNEF and 301 with asymptomatic LVDD). LA longitudinal systolic (LA late diastolic strain rate) and diastolic (LA systolic strain and strain rate) function was significantly more impaired in patients with HFNEF (LA late diastolic strain rate, -1.17 +/- 0.63 s(-1); LA systolic strain, 19.9 +/- 7.3%; LA systolic strain rate, 1.17 +/- 0.46 s(-1)) compared with those with asymptomatic LVDD (-1.80 +/- 0.70 s(-1), 30.8 +/- 11.4%, and 1.67 +/- 0.59 s(-1), respectively) (all P values &lt; .0001). On multiple regression analysis, LV global longitudinal systolic strain and diastolic strain rate were the most important independent predictors of LA longitudinal systolic and diastolic function, in contrast to noninvasive LV filling pressures (i.e., mitral E/e’ average septal-lateral ratio), which were modestly related to LA longitudinal systolic and diastolic function. Furthermore, in patients with HFNEF, the subendocardial function of both the left atrium and the left ventricle was significantly impaired in high proportions. In that regard, in patients with HFNEF, the rate of LA longitudinal systolic and diastolic dysfunction was 65.5% and 28.5%, whereas the prevalence of LV longitudinal systolic and diastolic dysfunction was 81.5% and 58%, respectively. In addition, patients with both systolic and diastolic longitudinal dysfunction of the left atrium presented worse NYHA functional class as compared with those with normal LA longitudinal function.</td>

<td>Review/Ot her-Dx</td>
<td>98 patients; 16 controls</td>
<td>To determine the prevalence of isolated exercise-induced heart failure with normal ejection fraction (HFNEF) and to assess whether disturbances in left ventricular (LV) or right ventricular longitudinal systolic function are associated with the diagnosis of HFNEF.</td>
<td>Eighty-four patients with exertional dyspnoea and normal left ventricular ejection fraction (LV EF) and 14 healthy controls underwent spirometry, NT-proBNP plasma analysis, and exercise echocardiography. Doppler LV inflow and tissue mitral and tricuspid annular velocities were analysed at rest and immediately after the termination of exercise. Of the 30 patients with the evidence of HFNEF, 6 (20%) patients had only isolated exercise-induced HFNEF. When compared with the remaining patients, those with HFNEF had a significantly lower resting and exercise peak mitral annular systolic velocity (Sa) and the mitral annular velocity during atrial contraction, lower exercise peak mitral annular velocity at early diastole, and lower exercise peak systolic velocity of tricuspid annular motion. The multivariate logistic regression analysis including both parameters standardly defining HFNEF and the new Doppler variables potentially associated with the diagnosis of HFNEF revealed that NT-proBNP, LV mass index, left atrial volume index, and Sa significantly and independently predict the diagnosis of HFNEF.</td>

<td>79. Donal E, Thebault C, Lund LH, et al. Heart failure with a preserved ejection fraction additive value of an exercise stress echocardiography. Eur Heart J Cardiovasc Imaging. 2012;13(8):656-665.</td>
<td>Observational-Dx</td>
<td>21 patients; 15 controls</td>
<td>To analyse the myocardial characteristics at rest and during a sub-maximal exercise test in patients with Heart failure preserved ejection fraction (HFPEF).</td>
<td>Standardized sub-maximal exercise stress echocardiography was performed in (i) 21 patients from the Karolinska Rennes Prospective Study of Heart Failure with Preserved Left Ventricular Ejection Fraction HFPEF registry, whose LVEF was &gt;/=45% and (ii) 15 control patients free of any manifestations of HF. During a sub-maximal exercise test, LV systolic function measured as a global four-chamber longitudinal strain was -17+/−5% in patients with HFPEF vs. -22+/−4% in controls (P&lt;0.001), LV longitudinal diastolic relaxation, expressed as e’ (septal and lateral walls averaged) was 9+/−2 cm/s in patients vs. 15+/−4 cm/s in controls (P&lt;0.001), and RV longitudinal systolic function, expressed as RV s’, was 14+/−3 cm/s in patients vs. 18+/−1 cm/s in controls (P=0.03). LV afterload (arterial elastance) was 2.7+/−1 mmHg/mL and was correlated with a decrease in LV longitudinal strain (R=0.51, P&lt;0.01) during exercise.</td>

<td>80. Bhella PS, Pacini EL, Prasad A, et al. Echocardiographic indices do not reliably track changes in left-sided filling pressure in healthy subjects or patients with heart failure with preserved ejection fraction. Circ Cardiovasc Imaging. 2011;4(5):482-489.</td>
<td>Observational-Dx</td>
<td>47 patients</td>
<td>To estimate changes in filling pressures associated with the titration of medical therapy in patients with heart failure.</td>
<td>Forty-seven volunteers were enrolled: 11 highly screened elderly outpatients with a clear diagnosis of heart failure with preserved ejection fraction (HFP EF), 24 healthy elderly subjects, and 12 healthy young subjects. Each patient underwent right heart catheterization with simultaneous transthoracic echo. Pulmonary capillary wedge pressure (PCWP) and key echo indices (E/e' and E/Vp) were measured at two baselines and during 4 preload altering maneuvers: lower body negative pressure -15 mm Hg; lower body negative pressure -30 mm Hg; rapid saline infusion of 10 to 15 mL/kg; and rapid saline infusion of 20 to 30 mL/kg. A random coefficient mixed model regression of PCWP versus E/e' and PCWP versus E/Vp was performed for (1) a composite of all data points and (2) a composite of all data points within each of the 3 groups. Linear regression analysis was performed for individual subjects. With this protocol, PCWP was manipulated from 0.8 to 28.8 mm Hg. For E/e', the composite random effects mixed model regression was PCWP=0.58xE/e'+7.02 (P&lt;0.001), confirming the weak but significant relationship between these 2 variables. Individual subject linear regression slopes (range, -6.76 to 11.03) and r(2) (0.00 to 0.94) were highly variable and often very different than those derived for the composite and group regressions. For E/Vp, the composite random coefficient mixed model regression was PCWP=1.95xE/Vp+7.48 (P=0.005); once again, individual subject linear regression slopes (range, -16.42 to 25.39) and r(2) (range, 0.02 to 0.94) were highly variable and often very different than those derived.</td>

<td>81. Sharifov OF, Schiros CG, Aban I, Denney TS, Gupta H. Diagnostic Accuracy of Tissue Doppler Index E/e' for Evaluating Left Ventricular Filling Pressure and Diastolic Dysfunction/Heart Failure With Preserved Ejection Fraction: A Systematic Review and Meta-Analysis. J Am Heart Assoc. 2016;5(1).</td>
<td>Meta-analysis</td>
<td>24 studies</td>
<td>To review the Diagnostic Accuracy of Tissue Doppler Index E/e' for Evaluating Left Ventricular Filling Pressure and Diastolic Dysfunction/Heart Failure With Preserved Ejection Fraction</td>
<td>From the PubMed, Scopus, Embase, and Cochrane databases, we identified 24 studies reporting E/e' and invasive LVFP in preserved EF (&gt;=50%). In random-effects models, E/e' had poor to mediocre linear correlation with LVFP. Summary sensitivity and specificity (with 95% CIs) for the American Society of Echocardiography-recommended E/e' cutoffs (lateral, mean, and septal, respectively) to identify elevated LVFP was estimated by using hierarchical summary receiver operating characteristic analysis. Summary sensitivity was 30% (9-48%), 37% (13-61%), and 24% (6-46%), and summary specificity was 92% (82-100%), 91% (80-99%), and 98% (92-100%). Positive likelihood ratio (LR+) was &lt;5 for lateral and mean E/e'. LR+ was slightly &gt;10 for septal E/e' obtained from 4 studies (cumulative sample size &lt;220). For excluding elevated LVFP, summary sensitivity for E/e' (lateral, mean, and septal, respectively) was 64% (38-86%), 36% (3-74%), and 50% (14-81%), while summary specificity was 73% (54-89%), 83% (49-100%), and 89% (66-100%). Because of data set limitations, meaningful inference for identifying HFpEF by using E/e' could not be drawn. With the use of quality assessment tool for diagnostic accuracy studies (Quality Assessment of Diagnostic Accuracy Studies questionnaire), we found substantial risks of bias and/or applicability.</td>

<td>83. Donal E, Lund LH, Oger E, et al. Value of exercise echocardiography in heart failure with preserved ejection fraction: a substudy from the KaRen study. Eur Heart J Cardiovasc Imaging. 2016;17(1):106-113.</td>
<td>Observatio nal-Dx</td>
<td>203 patients</td>
<td>To describe and analyse the potential prognostic value of echocardiographic parameters recorded not only at rest but also during a submaximal exercise stress echocardiography.</td>
<td>Patients were prospectively recruited in a single tertiary centre following an acute HF episode with NT-pro-BNP &gt;300 pg/mL (BNP &gt; 100 pg/mL) and LVEF &gt; 45% and reassessed by exercise echo-Doppler after 4-8 weeks of dedicated treatment. Image acquisitions were standardized, and analysis made at end of follow-up blinded to patients' clinical status and outcome. In total, 60 patients having standardized echocardiographic acquisitions were included in the analysis. Twenty-six patients (43%) died or were hospitalized for HF (primary outcome). The mean +/- SD workload was 45 +/- 14 watts (W). Mean +/- SD resting LVEF and LV global longitudinal strain was 57.6 +/- 9.5% and -14.5 +/- 4.2%, respectively. Mean +/- SD resting E/e' was 11.3 +/- 4.7 and 13.1 +/- 5.3 in those patients who did not and those who did experience the primary outcome, respectively (P = 0.03). Tricuspid regurgitation (TR) peak velocity during exercise were 3.3 +/- 0.5 and 3.7 +/- 0.5 m/s (P = 0.01). Exercise TR was independently associated with HF-hospitalization or death after adjustment on baseline clinical and biological characteristics.</td>

<td>84. Freed BH, Daruwalla V, Cheng JY, et al. Prognostic Utility and Clinical Significance of Cardiac Mechanics in Heart Failure With Preserved Ejection Fraction: Importance of Left Atrial Strain. Circ Cardiovasc Imaging. 2016;9(3):1-10.</td>
<td>Observational-Dx</td>
<td>308 patients</td>
<td>To (1) determine the clinical, invasive hemodynamic, and cardiopulmonary exercise testing (CPET) correlates of left atrium (LA) strain in heart failure with preserved ejection fraction (HFpEF); and (2) evaluate the prognostic utility of LA strain in HFpEF and determine its significance when compared with conventional echocardiographic and clinical factors, and indices of left ventricular (LV) and right ventricular (RV) mechanics.</td>
<td>We evaluated baseline LA function in 308 patients with HFpEF who were followed up longitudinally for adverse outcomes. All patients underwent speckle-tracking echocardiography for measurement of left ventricular longitudinal strain, right ventricular free wall strain, and LA booster, conduit, and reservoir strains. The clinical and prognostic significance of left ventricular, right ventricular, and LA strain measures was assessed by regression analyses. The mean age was 65+/-13 years, 64% were women, 26% had atrial fibrillation, and LA enlargement was present in the majority of patients (67%). Decreased LA reservoir strain was associated with increased pulmonary vascular resistance (P&lt;0.0001) and decreased peak oxygen consumption (P=0.0001). Of the left ventricular, right ventricular, and LA strain measures, LA reservoir strain was the strongest correlate of adverse events and was independently associated with the composite outcome of cardiovascular hospitalization or death (adjusted hazard ratio per 1-SD decrease in LA strain, 1.54; 95% CI, 1.15-2.07; P=0.006).</td>

<td>95. Beton O, Kurmus O, Asarcikli LD, Alibazoglu B, Alibazoglu H, Yilmaz MB. The practical value of technetium-99m-MIBI SPET to differentiate between ischemic and non-ischemic heart failure presenting with exertional dyspnea. Hell J Nucl Med. 2016;19(2):147-154.</td>
<td>Observational-Dx</td>
<td>179 patients</td>
<td>To differentiate ischemic heart failure (HF) from non-ischemic HF in patients presenting with non-acute onset exertional dyspnea using technetium-99m methoxyisobutylisonitrile gated single photon emission tomography ((99m)Tc-MIBI gSPET) imaging.</td>
<td>Of the 179 patients, 127 had ischemic HF and 52 had non-ischemic HF. There was no difference between ischemic and non-ischemic groups in terms of age, gender, body mass index, any smoking history, diabetes mellitus, history of hypertension and hyperlipidemia. Global dysfunction of left ventricle was more common in non-ischemic HF group than ischemic HF group (82.7% vs 41.7% respectively, P&lt;0.001). Presence of severe (3+/4+) ischemia and large perfusion defect were higher in ischemic HF group compared to non-ischemic HF group (45.7% vs 15.4%, P&lt;0.001 and 23.6% vs 3.8%, P=0.003, respectively). Summed stress score (SSS), summed rest score and summed difference score were higher in ischemic HF group compared to non-ischemic HF group (P&lt;0.001, P&lt;0.001, and P=0.021, respectively). In multivariate analysis, absence of global dysfunction (P&lt;0.001, OR=10.338, 95% CI: 3.937-27.405) and SSS (P&lt;0.001, OR=1.208, 95% CI: 1.090-1.339) were the independent predictors of ischemic HF. Absence of global dysfunction had 58.3% sensitivity and 86.7% specificity for diagnosis of ischemic HF at gSPET imaging in patients presenting with newly diagnosed HF and exertional dyspnea without concomitant chest pain (AUC=0.705, 95% CI: 0.632-0.771, P&lt;0.001), whereas SSS&gt;8 had 65.4% sensitivity and 75.0% specificity (AUC=0.732, 95% CI: 0.661-0.795, P&lt;0.001).</td>

<td>Observational-Dx</td>
<td>124 patients</td>
<td>To assess the diagnostic accuracy of a cardiovascular magnetic resonance (CMR) protocol incorporating late gadolinium enhancement (LGE) and magnetic resonance coronary angiography (CA) as a noninvasive gatekeeper to CA in determining the etiology of heart failure in this subset of patients.</td>
<td>One hundred twenty consecutive patients underwent CMR and CA. The etiology was ascribed by a consensus panel that used the results of the CMR scans. Similarly, a separate consensus group ascribed an underlying cause by using the results of CA. The diagnostic accuracy of both strategies was compared against a gold-standard panel that made a definitive judgment by reviewing all clinical data. The study was powered to show noninferiority between the 2 techniques. The sensitivity of 100%, specificity of 96%, and diagnostic accuracy of 97% for LGE-CMR were equivalent to CA (sensitivity, 93%; specificity, 96%; and diagnostic accuracy, 95%). As a gatekeeper to CA, LGE-CMR was also found to be a cheaper diagnostic strategy in a decision tree model when United Kingdom-based costs were assumed. The economic merits of this model would change, depending on the relative costs of LGE-CMR and CA in any specific healthcare system.</td>

<td>28 patients</td>
<td>To prospectively compare standard-of-care invasive catheter angiography (iCA) and echocardiography to a novel non-invasive strategy of both Coronary Computed Tomographic Angiography (CCTA) and Cardiovascular MRI (CMR) to determine the etiology of myocardial dysfunction.</td>
<td>426 coronary segments from 28 prospectively enrolled patients were analyzed by CCTA and quantitative iCA. The per-patient sensitivity and specificity of CCTA was 100% and 90%, respectively, negative predictive value (NPV) 100%, positive predictive value (PPV) 78%. Mean ejection fraction by CMR was 24%. Presence of ischemic-type LGE on CMR conferred a 67% sensitivity, 100% specificity, 90% NPV and 100% PPV. Combining CCTA with CMR conferred 100% specificity, 100% sensitivity, 100% PPV and 100% NPV for detection or exclusion of coronary disease. In patients with negative CCTA all invasive angiograms could have been avoided. In addition, two patients with no ischemic LGE by CMR had severe coronary disease on both CCTA and iCA, indicating global hibernation.</td>

<td>101. ten Kate GJ, Caliskan K, Dedic A, et al. Computed tomography coronary imaging as a gatekeeper for invasive coronary angiography in patients with newly diagnosed heart failure of unknown aetiology. Eur J Heart Fail. 2013;15(9):1028-1034.</td>
<td>Observatio nal-Dx</td>
<td>81 patients</td>
<td>To evaluate the accuracy of cardiac computed tomography (CT) in distinguishing Coronary Artery Disease (CAD) and non-CAD heart failure (HF) and its effectiveness as a gatekeeper for invasive coronary angiography (ICA).</td>
<td>We prospectively included 93 symptomatic patients with newly diagnosed HF of unknown aetiology (59 men; mean age 53 +/- 13) and EF &lt;45%, and/or fractional shortening &lt;25%, and/or end-diastolic LV diameter &gt;60 mm (men) or &gt;55 mm (women). In all patients, the CT calcium score (CTCS) was determined. CTCS = 0 excluded CAD HF. Additional CT coronary angiography (CTCA) was performed if CTCS &gt;0. ICA was used as the gold standard for distinguishing between CAD and non-CAD HF in patients with &gt;20% luminal diameter narrowing on CTCA. CAD HF was defined as &gt;50% luminal diameter narrowing in either (i) the left main coronary artery or proximal left anterior descending coronary artery or (ii) in multiple coronary arteries. Diagnostic accuracy and follow-up data (20 +/- 16 months) were collected for all patients. CTCS = 0 ruled out CAD HF in 43 patients (46%). The CT algorithm had 100% sensitivity, 95% specificity, 67% positive predictive value, and 100% negative predictive value for detecting CAD HF. Patients with CTCS = 0 or non-CAD HF on CTCA had no coronary events during follow-up, and ICA could have been safely avoided in 76 out of 93 patients (82%).</td>

<td>102. Abunassar JG, Yam Y, Chen L, D'Mello N, Chow BJ. Usefulness of the Agatston score = 0 to exclude ischemic cardiomyopathy in patients with heart failure. Am J Cardiol. 2011;107(3):428-432.</td>
<td>Observational-Dx</td>
<td>738 patients</td>
<td>To understand the potential application of the Agatston score in patients with heart failure (HF)</td>
<td>Excluding patients with HF or LV dysfunction, 738 patients (mean age 52 ± 10 years, 43% men) had an Agatston score equal to 0. Of these, 18 (2%) had obstructive CAD (diameter stenosis ≥50%), 8 (1%) had diameter stenoses ≥70%, and none had high-risk CAD. The 74 patients with high-risk CAD without LV dysfunction had high Agatston scores (mean 895 ± 734, median 716, range 50 to 3,210). In total 153 patients with a history of HF and abnormal ejection fraction were identified. All 13 patients with ischemic cardiomyopathy had Agatston scores &gt;0, whereas 46 of 140 patients (30.1%) with nonischemic causes had an Agatston score equal to 0. An Agatston score equal to 0 identified nonischemic causes with a specificity of 100% (confidence interval 90 to 100) and positive predictive value of 100% (confidence interval 90 to 100). Agatston score equal to 0 had incremental value to pretest probability for CAD.</td>

<td>Review/Ot her-Dx</td>
<td>754 patients</td>
<td>To determine the utility of an Agatston score equal 0 to exclude the diagnosis of ischemic cardiomyopathy</td>
<td>Eighty-two patients were enrolled in the study and underwent CAC imaging with 81.7% patients having non-ischemic cardiomyopathy. An Agatston score=0 successfully excluded an ischemic etiology for cardiomyopathy with a specificity of 100% (CI: 74.7-100%) and a positive predictive value of 100% (CI: 85.0%-100%). A systematic literature review was performed and studies were deemed suitable for inclusion if: 1) patients with CHF, cardiomyopathy or LV dysfunction were enrolled, 2) underwent CAC imaging and patients were assessed for an Agatston score=0 or the absence of CAC, and 3) the final etiologic diagnosis (ischemic or non-ischemic) was provided. Eight studies provided sufficient information to calculate operating characteristics for an Agatston score=0 and were combined with our validation cohort for a total of 754 patients. An Agatston score=0 excluded ischemic cardiomyopathy with specificity and positive predictive values of 98.4% (CI: 95.6-99.5%), and 98.3% (CI: 95.5-99.5%), respectively.</td>

### Reference 104.

**Study Type:** Observational-Dx

**Patients/Events:** 100 patients

**Study Objective (Purpose of Study):** To assess the value of coronary multidetector computed tomography (MDCT) angiography in the exclusion of ischemic etiology in heart failure (HF) patients and to determine whether the Agatston calcium score could be used as a gatekeeper for CTA in this context.

**Study Results:** During this period 100 patients (mean age 57.3±10.5 years, 64% men) with HF and systolic dysfunction were referred for MDCT to exclude CAD. Median effective radiation dose was 4.8 mSv (interquartile range 5.8 mSv). Mean LVEF was 35±7.7% (range 20-48%) and median CAC score was 13 (interquartile range 212). Seven patients were in atrial fibrillation. Almost half of the patients (40%) had no CAC and none of these had significant stenosis on CTA. In an additional group of 33 patients CTA was able to confidently exclude obstructive CAD. Twenty-seven patients were classified as positive for CAD (16 due to CAC >400 and 11 with =50% stenosis) and were associated with lower LVEF (p=0.004). Of these, 21 patients subsequently underwent ICA: obstructive CAD was confirmed in nine and only six had criteria for ischemic cardiomyopathy.

**Study Quality:** 3

### Reference 105.

**Study Type:** Review/Other-Dx

**Patients/Events:** 107 patients

**Study Objective (Purpose of Study):** To evaluate the prevalence of ischemic heart disease by angiographic criteria in patients with heart failure and reduced ejection fraction of unknown etiology, as well as its impact on therapy decisions.

**Study Results:** One hundred and seven patients were included in the analysis, with 51 (47.7%) patients in Group 1 and 56 (52.3%) in Group 2. The prevalence of ischemic heart disease was 9.3% (10 patients), and all belonged to Group 1 (p = 0.0001). During follow-up, only 4 (3.7%) were referred for CABG; 3 (2.8%) patients had procedure-related complications.

**Study Quality:** 4

### Reference 106.

**Study Type:** Review/Other-Dx

**Patients/Events:** N/A

**Study Objective (Purpose of Study):** Guidance document on exposure of patients to ionizing radiation.

**Study Results:** No results stated in abstract.

**Study Quality:** 4
**Evidence Table Key**

**Study Quality Category Definitions**

- **Category 1**  The study is well-designed and accounts for common biases.
- **Category 2**  The study is moderately well-designed and accounts for most common biases.
- **Category 3**  There are important study design limitations.
- **Category 4**  The study is not useful as primary evidence. The article may not be a clinical study or the study design is invalid, or conclusions are based on expert consensus. For example:
  - a. The study does not meet the criteria for or is not a hypothesis-based clinical study (e.g., a book chapter or case report or case series description);
  - b. The study may synthesize and draw conclusions about several studies such as a literature review article or book chapter but is not primary evidence;
  - c. The study is an expert opinion or consensus document.
- **Meta-analysis**
  - a. *Good quality* – the study design, methods, analysis, and results are valid and the conclusion is supported.
  - b. *Inadequate quality* – the study design, analysis, and results lack the methodological rigor to be considered a good meta-analysis study.
