<td>Review/Other-Dx</td>
<td>N/A</td>
<td>To review ONFH.</td>
<td>New cases of ONFH in the United States number between 10,000 and 20,000 per year. This disease usually affects patients in their late 30s and early 40s. Although a number of authors have related specific risk factors to this disease, its etiology, pathogenesis, and treatment remain a source of considerable controversy. This disorder has been associated with corticosteroid use, substance abuse, and various systemic medical conditions. Either direct damage to osteocytes (eg, by toxin production) or indirect damage (eg, due to disorders in fat metabolism or hypoxia) may lead to osteonecrosis.</td>

<td>6. Hauzeur JP, Pasteels JL, Schoutens A, et al. The diagnostic value of magnetic resonance imaging in non-traumatic osteonecrosis of the femoral head. <em>J Bone Joint Surg Am.</em> 1989;71(5):641-649.</td>
<td>Review/Other-Dx</td>
<td>25 patients</td>
<td>To assess the effectiveness of nuclear MRI in the detection of ONFH.</td>
<td>Of the 49 hips, 33 had histological proof of osteonecrosis. 22 (67%) of these hips showed definite necrosis on the plain radiographs; 18 (62%), on the 29 available CT scans; 24 (77%), on the 31 available radionuclide bone scans; and all of the hips, on the MRI studies. In 6 additional hips, there were histological changes (marrow necrosis, edema, hemorrhage, and fibrosis) in the medullary spaces without detectable osteonecrosis. The plain radiographs and CT scans of these 6 hips were normal except for the CT scan of 1, and the radionuclide uptake on bone-scanning was abnormal in 4 of the 6, as were the MRI studies. In the 2 hips that had normal MRI studies, the biopsies showed only destruction of fat cells in the medullary spaces, with no edema or fibroblastic reaction.</td>

<tr>
<td>7. Stevens K, Tao C, Lee SU, et al. Subchondral fractures in osteonecrosis of the femoral head: comparison of radiography, CT, and MR imaging. <em>AJR Am J Roentgenol.</em> 2003;180(2):363-368.</td>
<td>Observational-Dx</td>
<td>45 patients</td>
<td>To compare the sensitivity of unenhanced radiography, CT, and MRI in revealing subchondral fractures.</td>
<td>At 6 months, 18 fractures were shown on CT scans, but only 12 were detected on radiographs, and 6 on MRIs. At 12 months, 20 subchondral fractures were detected on CT scans, but only 17 were seen on radiographs and 11, on MRIs. Compared with CT, MRI has a sensitivity and specificity of 38% and 100%, and unenhanced radiography has a sensitivity and specificity of 71% and 97%, respectively. On T2-weighted MRIs, the subchondral fractures were visualized as crescentic high-signal-intensity lines, and in all patients, on the corresponding CT scans, the fracture clearly breached the femoral cortex.</td>

<td>Review/Other-Tx</td>
<td>39 patients</td>
<td>To retrospectively review patients in whom a modified transtrochanteric rotational osteotomy was performed for osteonecrosis.</td>
<td>The minimum follow-up was 24 months. Based on the ARCO classification, 17 hips were classified as stage II and 26 as stage III. We performed rotational osteotomy alone in 15 cases, in combination with simple bone grafting in 3, and in combination with muscle-pedicle-bone grafting in 25. 16/17 ARCO stage II cases and 24/26 ARCO stage III cases had no progression of collapse or lesion size; 3 hips progressively collapsed. Of the 40 hips without progression, the Harris hip score improved from a mean 70 to 92 points at final follow-up, as did the range of motion of the hip. Modified transtrochanteric rotational osteotomy is an effective method for delaying the progression of collapse in the treatment of selected cases of ONFH.</td>

<td>Review/Other-Dx</td>
<td>N/A</td>
<td>To describe an image analysis method that evaluates bone morphology of hip structures including the femur stem, trochanter, neck and head, acetabulum, and pelvis to automate hip diagnoses and surgical managements.</td>
<td>On every CT transverse section, radial B-spline curves are used to approximate the ellipse-like acetabulum and femur head and stem. The femur neck is approximated as trapezoid-like and the pelvis horizontally symmetrical structure. The centers of the ellipse-like structures from transverse sections are used to determine 3-D axes of the femur stem, head, and acetabulum. The centerlines of the neck or the pelvis on the sections are used to determine the neck axis or pelvis centerplane. Boundary changes of these structures are recognized as concave, convex and hole features that are then identified as fractures, tumors, and spurs. Based on the geometric evaluations of these structures and features, hip surgeries including tumor dissection and bone graft, open reduction using plates, screws and nails, and arthroplasty are automatically managed to achieve the normal hip function including dissection of tumors and reduction of dislocations and angular deviations between the hip structures.</td>

<td>Review/Other-Dx</td>
<td>45 patients (77 hips)</td>
<td>To assess multimodal imaging quantitation of the lesion size in ONFH.</td>
<td>Patients with ONFH were evaluated using a multimodal imaging approach that included conventional radiography, bone scintigraphy, and MRI. A computerized image analysis program that allowed quantification of the lesion size on radiographs and MRIs was used. Measurements of the extent of involvement on radiographs and selected serial MRIs were compared in 33 hips (42.9%) before collapse vs 44 hips (57.1%) after collapse. The size of the necrotic lesion varied significantly according to the specific stage of disease. Quantification of the lesion during the course of the disease provided a record of the progression of osteonecrosis, despite a spurious stability in staging. In general, conventional radiography closely approximated measurements of the lesion size obtained by MRI. Bone scintigraphy and MRI were well suited for detection of osteonecrosis at an early stage. Finally, precise quantification of the lesion size was an optimal preoperative means for evaluating the extent of involvement of the femoral head in the early and advanced stages of osteonecrosis.</td>

<td>Observational-Dx</td>
<td>24 patients</td>
<td>To compare the diagnostic sensitivity of Tc99m-MDP bone SPECT and MRI in the early detection of femoral head osteonecrosis after renal transplantation.</td>
<td>A total of 32 femoral heads, including 24/29 painful hips and 8/19 asymptomatic contralateral hips, were confirmed as having osteonecrosis. SPECT detected osteonecrosis in all 32 of the femoral heads, resulting in a sensitivity of 100% (32/32), whereas MRI detected osteonecrosis in 21 femoral heads, for a sensitivity of 66% (21/32, <em>P</em>&lt;0.005). SPECT showed the type 1 pattern in 13 and the type 2 in 19. 10/13 femoral heads with the type 1 pattern were false-negative on MRI, whereas only 1 of 19 with the type 2 pattern was normal on MRI (<em>P</em>&lt;0.001). There were 6 femoral heads with normal MRI findings and abnormal SPECT findings (type 1 pattern) in 3 patients, for whom hip pain decreased and radiographic findings were normal during follow-up. Follow-up bone SPECT showed a decreasing area of cold defect in 4 femoral heads.</td>

<td>16. Scheiber C, Meyer ME, Dumitresco B, et al. The pitfalls of planar three-phase bone scintigraphy in nontraumatic hip avascular osteonecrosis. <em>Clin Nucl Med.</em> 1999;24(7):488-494.</td>
<td>Observational-Dx</td>
<td>143 patients</td>
<td>To document the previously reported lower sensitivity of routine planar three-phase bone scintigraphy performed using a high-resolution parallel-hole collimator compared with MRI to diagnose nontraumatic AVN of the hip.</td>
<td>For the 6 observers, the A(2) values were 0.65, 0.67, 0.66, 0.67, 0.73, and 0.79, respectively, and 0.66, 0.71, 0.75, 0.81, 0.81, 0.82, and 0.84 after removing hip diseases other than AVN through data manipulation. Bone marrow edema, as seen on MRI, was the most frequently reported misleading sign in false-positive diagnoses, especially in the early or late phases of the disease. False-negative diagnoses misclassified the scans as “asymptomatic hips” in 28/30 cases. 22/30 scans appeared normal, but these AVN lesions were small (&lt;25%) and were discovered by chance on MRIs that displayed bilateral involvement associated with radiographic evidence (stage 0 or 1). 13/20 patients were followed for 3 or more years, and only 1 worsened.</td>

<td>20. Ikemura S, Yamamoto T, Motomura G, Nakashima Y, Mawatari T, Iwamoto Y. MRI evaluation of collapsed femoral heads in patients 60 years old or older: Differentiation of subchondral insufficiency fracture from osteonecrosis of the femoral head. <em>AJR Am J Roentgenol.</em> 2010;195(1):W63-68.</td>
<td>Observational-Dx</td>
<td>30 consecutive hips in 30 patients</td>
<td>To verify the hypothesis that osteonecrosis and subchondral insufficiency fracture of the femoral head can be differentiated on the basis of their appearance on MRI.</td>
<td>16 hips (53.3%) showed evidence of osteonecrosis and 14 (46.7%) showed evidence of subchondral insufficiency fracture, which was consistent with the corresponding histopathologic diagnoses. In all cases of osteonecrosis, the patient had a history of either corticosteroid intake or alcohol abuse. Among patients with subchondral insufficiency fracture, the proportion of women was significantly higher than that among patients with osteonecrosis. A crescent sign (subchondral fracture) was present radiographically in about half of all cases in both groups.</td>

<td>22. Kim YM, Oh HC, Kim HJ. The pattern of bone marrow oedema on MRI in osteonecrosis of the femoral head. J Bone Joint Surg Br. 2000;82(6):837-841.</td>
<td>Review/Other-Dx</td>
<td>200 patients</td>
<td>To evaluate the MRI of ONFH with particular attention to the bone marrow oedema pattern, to determine if there is any evidence to support the concept of a continuum between transient osteoporosis and osteonecrosis.</td>
<td>The MRIs of consecutive patients with ONFH in respect of the bone marrow oedema pattern were assessed. This pattern was not observed in the early stage of ONFH. The initial abnormal finding detected on the MRIs was an abnormal band of intensity at the junction between the necrotic area and the normal bone. Structural damage of the head seems to result in the appearance of the bone marrow oedema pattern and the development of pain in ONFH. There was no finding to support the existence of a continuum between bone marrow oedemas and ONFH.</td>

<td>Observational-Dx</td>
<td>42 patients</td>
<td>To describe the MRI findings including perfusion imaging, in association with the course of acute bone marrow oedema syndrome, in a group of patients with acute hip pain and a final diagnosis of TOH.</td>
<td>Osteopenia was present on plain radiographs in 87% of cases. The most common pattern of bone marrow oedema was extending to the femoral head and neck. Acetabulum was involved in 16.6%. In 22.6% the bone marrow oedema spared the subchondral region of the femoral head. There were 2 cases (4.7%) with subchondral changes. A joint effusion was noted in 33/42 patients. On perfusion imaging, a delayed peak enhancement was noted in 20 patients between 40 and 65 s after the first pass of contrast. No patient had any evidence of femoral head collapse or change in sphericity on follow-up MRI. None of the patients developed AVN in a time frame of 18 months from the onset of the acute hip pain.</td>

<td>Review/Other- Dx</td>
<td>N/A</td>
<td>To review bone marrow edema syndrome.</td>
<td>Bone marrow edema syndrome is primarily characterized by bone marrow edema pattern. The disease mainly affects the hip, the knee, and the ankle of middle-aged males. Many hypotheses have been proposed to explain the pathogenesis of the disease. Unfortunately, the etiology of bone marrow edema syndrome remains obscure. The hallmark that separates bone marrow edema syndrome from other conditions presented with bone marrow edema pattern is its self-limited nature. Laboratory tests usually do not contribute to the diagnosis. Histological examination of the lesion is unnecessary. Plain radiographs may reveal regional osseous demineralization. MRI is mainly used for the early diagnosis and monitoring the progression of the disease. Early differentiation from other aggressive conditions with long-term sequelae is essential in order to avoid unnecessary treatment. Clinical entities, such as TOH, migratory osteoporosis, and reflex sympathetic dystrophy are spontaneously resolving, and surgical treatment is not needed. On the other hand, early differential diagnosis and surgical treatment in case of osteonecrosis is of crucial importance.</td>

<td>30. Du J, Lu A, Dempsey M, Herring JA, Kim HK. MR perfusion index as a quantitative method of evaluating epiphyseal perfusion in Legg-Calve-Perthes disease and correlation with short-term radiographic outcome: a preliminary study. <em>J Pediatr Orthop.</em> 2013;33(7):707-713.</td>
<td>Observational-Dx</td>
<td>20 patients</td>
<td>To develop a reliable method to quantify femoral head perfusion using this MRI technique and to determine whether the perfusion at early stages of Perthes disease correlates with radiographic deformity after a 2-year follow-up.</td>
<td>The intraobserver agreement assessed by the intraclass correlation coefficient was 0.96 for observer 1 and 0.97 for observer 2. The interobserver agreement of the MR perfusion index was 0.90 for trials 1 and 2. MR perfusion index in the early stages of Perthes disease was highly variable, ranging from 0 to 0.70. After a minimum of 2 years following MRI acquisition, radiographs were obtained and evaluated using the deformity index, a continuous measure of femoral head deformity, by 2 blinded observers. Deformity index at 2-year follow-up showed moderate correlation with predeformity MR perfusion index (r=-0.56, P&lt;0.01, R=0.31). In those patients who were treated nonoperatively, the correlation was stronger (r=-0.79, P&lt;0.006, R=0.63).</td>

<td>32. Kaushik A, Sankaran B, Varghese M. Prognostic value of dynamic MRI in assessing post-traumatic femoral head vascularity. <em>Skeletal Radiol.</em> 2009;38(6):565-569.</td>
<td>Observational-Dx</td>
<td>30 patients with 31 hips</td>
<td>To evaluate the role of dynamic MRI in predicting femoral head vascularity and thereby AVN after intracapsular femoral neck fractures.</td>
<td>Fractures were divided into 3 types (Type A, B, or C) based on the femoral head head vascularity shown by dynamic curve patterns on MRI evaluation. Type A was preserved vascularity, Type B was some decrease in vascularity but still viable while Type C was significantly reduced vascularity. Type A curves correlate well with vascular status and Type C curves correlate well with poor vascularity of the femoral heads. No AVN was seen in any of Type A (13/31) or Type B (8/31). 5 cases showed AVN and all of them were of Type C dynamic curves. Dynamic MRI is a reliable tool to evaluate vascularity of femoral heads and thus reduces the uncertainty of outcome of treatment of intracapsular femoral neck fractures. Dynamic MRI can be a useful tool to formulate a treatment algorithm in management of intracapsular femoral neck fracture.</td>

<td>Experimental-Tx</td>
<td>20 patients</td>
<td>To evaluate hyperbaric oxygen therapy on a cohort of patients with femoral head necrosis.</td>
<td>Each patient received 30 treatments of hyperbaric oxygen or hyperbaric air for 6 weeks. Range of motion, stabilometry, and pain were assessed at the beginning of the study and after 10, 20, and 30 treatments by a blinded physician. After the initial 6-week treatment, the blind was broken; and all hyperbaric air patients were offered hyperbaric oxygen treatment. At this point, the study becomes observational. Pretreatment, 12-month and 7 year-follow-up MRIs were obtained. Statistical comparisons were obtained with nonparametric Mann-Whitney U test. Significant pain improvement for hyperbaric oxygen was demonstrated after 20 treatments. Range of motion improved significantly during hyperbaric oxygen for all parameters between 20 and 30 treatments. All patients remain substantially pain-free 7 years later: none required hip arthroplasty. Substantial radiographic healing of the osteonecrosis was observed in 7 of 9 hips.</td>

<td>Observational-Dx</td>
<td>109 patients</td>
<td>To examine the association between hip joint effusion volume and ONFH using the ARCO classification.</td>
<td>Out of 109 patients included in this study, 185 hip joints were involved (unilateral disease in 33 patients and bilateral diseases in 76 patients). The patients had a mean age of 39 +/- 11 years (range, 13–70). All the affected hip joints exhibited effusion, classified as grade 1 (n = 70, 37.8%), grade 2 (n = 62, 33.5%), and grade 3 (n = 53, 28.7%). The volume of joint effusion varied significantly among stage I, II, and III (X2 = 29.210, <em>P</em>&lt;0.05). The effusion volume did not differ significantly among stage IIA, IIB, and IIC (X2 = 0.103, <em>P</em>&gt;0.05), whereas it differed significantly among stage IIIA, IIB, and IIIIC (X2 =11.556, <em>P</em>&lt;0.05). The volume of hip joint effusion was associated with the ARCO stage, and increased over the staging.</td>

<td>43. Zhao FC, Li ZR, Zhang NF, et al. Lesion size changes in osteonecrosis of the femoral head: a long-term prospective study using MRI. <em>Int Orthop.</em> 2010;34(6):799-804.</td>
<td>Observational-Dx</td>
<td>51 patients</td>
<td>To use MRI to observe the lesion size changes of ONFH induced by corticosteroid administration in severe acute respiratory syndrome patients.</td>
<td>The study included 51 severe acute respiratory syndrome patients (84 hips) with early-stage ONFH who did not receive any operative treatment and were diagnosed by MRI. All of the patients underwent MRI follow-ups. Each patient was evaluated on the basis of the lesion volume on MRI at every follow-up for further comparisons. At the first MRI scan, the mean lesion volume was 10.12 +/- 8.05 cm$^3$ (range: 0.39–41.62 cm$^3$). At the mid-term follow-up (2.5 years), the mean lesion volume was 7.82 +/- 7.59 cm$^3$ (range: 0.11–39.65 cm$^3$). At the final follow-up (5 years), complete regression of the lesion was observed in 6 hips, and the mean lesion volume was 5.67 +/- 6.58 cm$^3$ (range: 0.00–31.47 cm$^3$). Overall, the lesion volume was reduced by &gt;15% in 80 hips, and only 4 hips with relatively larger lesion volumes showed no apparent reductions. The reduction in lesion size of ONFH observed on MRI is a slow, discontinuous and time-dependent process.</td>

<td>Observational-Tx</td>
<td>37 patients</td>
<td>To evaluate the outcome of core decompression in the asymptomatic hip with osteonecrosis.</td>
<td>37 consecutive patients with MRI confirmed osteonecrosis of the hips that underwent simultaneous bilateral core decompression and bone grafting were followed. Prior to surgery, only 1 of the hips was symptomatic, and the main indication for surgical decompression of the asymptomatic side was to prevent disease progression. No hip on the asymptomatic side was staged greater than Steinberg IIIB classification. Serial radiographs were followed for evidence of disease progression. 6 patients were lost to follow-up prior to 2 years. The remaining 31 patients were followed for an average of 32.6 months. There were 20 men and 11 women with an average age of 40.6 years. 10 patients with asymptomatic hips at the time of surgical decompression had disease progression requiring THA. The mean time to arthroplasty in this group was 15.1 months. Meanwhile, 13 symptomatic hips at the initial surgery progressed to THA at an average of 12.9 months following core decompression. The proportion of hips requiring conversion to THA was similar between the 2 groups (<em>P</em>=0.30), and the rate of progression to THA was not significantly faster compared to patients with symptomatic hips who subsequently required THA (<em>P</em>=0.18).</td>

<td>53. Yoshida T, Kanayama Y, Okamura M, Negoro N, Inoue T, Yoshikawa J. Long-term observation of avascular necrosis of the femoral head in systemic lupus erythematosus: an MRI study. Clin Exp Rheumatol. 2002;20(4):525-530.</td>
<td>Observational-Dx</td>
<td>13 patients</td>
<td>To assess long-term prognosis of clinically silent, early-stage AVN of the femoral head in patients with systemic lupus erythematosus.</td>
<td>15 hips improved (more than 15% reduction in the volume of necrosis), 5 did not change and 4 worsened during the observation period. All hips with a volume of necrotic area less than 25% showed improvement. All but 1 Type A hip and 1 Type B hip improved, while the mean volume of necrosis did not change in Type C. The volume of the necrotic area was smaller in Type A &amp; B than in Type C hips ($P&lt;0.001$).</td>

<td>54. Joseph B, Rao N, Mulpuri K, Varghese G, Nair S. How does a femoral varus osteotomy alter the natural evolution of Perthes' disease? J Pediatr Orthop B. 2005;14(1):10-15.</td>
<td>Review/Other-Dx</td>
<td>314 patients</td>
<td>To study how a femoral osteotomy alters the natural evolution of Perthes' disease, records and radiographs.</td>
<td>It was observed that a varus osteotomy clearly alters the natural evolution of Perthes' disease. Of patients who were operated in the stage of AVN, 34% bypassed the stage of fragmentation. The duration of the disease was shorter in these patients. The duration of the stage of fragmentation was reduced in operated children who passed through the stage of fragmentation. The extent of femoral head extrusion was minimized at the stage when it was most vulnerable for deformation. Metaphyseal widening and subsequent femoral head enlargement were also minimized in children who underwent a femoral osteotomy. The chances of retaining the sphericity of the femoral head were much higher in those children who had a femoral osteotomy. These beneficial effects of a varus osteotomy, were most evident when the operation was performed either in the stage of AVN or in the early stage of fragmentation.</td>

<td>Review/Other-Dx</td>
<td>121 patients</td>
<td>To review the natural history of asymptomatic osteonecrosis of the femoral head.</td>
<td>At the time of the initial evaluation, 56 hips were classified as Steinberg stage 0, 42 hips were classified as Steinberg stage I, and 23 hips were classified as Steinberg stage II. At the time of the most recent follow-up, pain had developed in 110 previously asymptomatic hips (91%) and collapse had occurred in 93 hips (77%). Symptoms always preceded collapse. Of the 56 hips that were classified as Steinberg stage 0 at the time of the initial evaluation, 47 (84%) had symptomatic osteonecrosis and 34 (61%) had collapse at the time of the most recent follow-up. Of the 42 asymptomatic stage-I hips, 40 (95%) became symptomatic within 3 years and 36 (86%) had collapse of the femoral head. Of the 23 asymptomatic stage-II hips, all became symptomatic within 2 years and all collapsed; the mean interval between the onset of pain and collapse was 11 months. At the time of the final follow-up, 91one hips (75%) had intractable pain and required surgery.</td>

<td>56. Nagasawa K, Tada Y, Koarada S, et al. Very early development of steroid-associated osteonecrosis of femoral head in systemic lupus erythematosus: prospective study by MRI. <em>Lupus.</em> 2005;14(5):385-390.</td>
<td>Observational-Dx</td>
<td>45 patients</td>
<td>To define prospectively the early development of corticosteroid-induced ONFH in patients with systemic lupus erythematosus and to identify the association of initial steroid treatment with the development of early (silent) ONFH.</td>
<td>Of 45 patients, 15 (33%) developed silent ONFH and 5 (11%) symptomatic ONFH. It was of interest that MRI detected silent ONFH very early (by 3 months) in 14 patients (93%). It should be noted that pulse therapy with 1000 mg/day methylprednisolone was found to be done very frequently (13/15, 87%) in the silent ONFH group compared to non-ONFH group (11/30, 37%) (<em>P</em>&lt;0.01) although other clinical features were not significantly different between both groups. High dose corticosteroids caused elevation of serum levels of total cholesterol, albumin, and leukocyte count in most of patients. The degree of elevation of those parameters at 1 or 3 months was more prominent in the silent ONFH group. In particular, the change ratio of total cholesterol at 1 month was outstanding in the silent ONFH group compared to non-ONFJ group (0.551 vs 0.374, <em>P</em>&lt;0.05).</td>

<td>57. Nadel SN, Debatin JF, Richardson WJ, et al. Detection of acute avascular necrosis of the femoral head in dogs: dynamic contrast-enhanced MR imaging vs spin-echo and STIR sequences. <em>AJR Am J Roentgenol.</em> 1992;159(6):1255-1261.</td>
<td>Observational-Dx</td>
<td>5 dogs</td>
<td>To compare dynamic contrast-enhanced MRI with conventional spin-echo and short T1 inversion-recovery sequences for detecting acute osteonecrosis in an animal model.</td>
<td>Spin-echo and spin-echo and short T1 inversion-recovery images did not show any acute changes in the ischemic femoral heads. In contrast, significant differences were present in the enhancement profiles of the marrow spaces in the normal and ischemic femoral heads (<em>P</em>=.005). Normal marrow was characterized by rapid enhancement, with an average signal intensity increase of 83% peaking at 36 sec; no measurable enhancement was seen in the marrow of the ischemic femoral head. Spin-echo images, obtained 7 days after devascularization (n = 2), showed changes characteristic of AVN. Dynamic contrast-enhanced MRIs showed persistent lack of enhancement in the avascular marrow of the ischemic femoral head. A junctional zone, characterized by rapid contrast enhancement in excess of 120% without early washout, was identified at the interface between normal and avascular marrow.</td>

<td>Review/Other-Dx</td>
<td>13 patients</td>
<td>To evaluate the use of MRI, before and after intravenous administration of gadopentetate dimeglumine, for assessing perfusion of the femoral head in 13 patients with acute fracture of the femoral neck.</td>
<td>Digital subtraction angiography showed impaired blood supply to the femoral head in 5 patients. On contrast-enhanced MRIs of these patients, the femoral head did not enhance and was lower in signal intensity than were the enhancing femoral shaft and neck distal to the fracture and the enhancing femoral head on the unaffected side. In the patients with persistent perfusion, contrast-enhanced MRIs showed a uniform increase in signal intensity in the femoral shaft and neck as well as the femoral head; the femoral head on the fractured side showed contrast enhancement similar to that on the healthy side.</td>

<td>60. Lamer S, Dorgeret S, Khairouni A, et al. Femoral head vascularisation in Legg-Calve-Perthes disease: comparison of dynamic gadolinium-enhanced subtraction MRI with bone scintigraphy. <em>Pediatr Radiol.</em> 2002;32(8):580-585.</td>
<td>Observational-Dx</td>
<td>23 children</td>
<td>To compare dynamic gadolinium-enhanced subtraction MRI and bone scintigraphy in the assessment of femoral head perfusion in Legg-Calve-Perthes disease.</td>
<td>Total agreement between both techniques was noted in the depiction of epiphyseal necrosis (kappa=1), and metaphyseal abnormalities (kappa=0.9). Dynamic gadolinium-enhanced subtraction MRI demonstrated better revascularization in the lateral (kappa=0.62) and medial pillars (kappa=0.52). The presence of basal transphyseal reperfusion was more conspicuous with MRI.</td>

<td>Observational-Dx</td>
<td>24 patients</td>
<td>To assess the potential correlation between the extent of AVN, as determined with preoperative MRI, and development of collapse.</td>
<td>The preoperative MR results were classified into 4 categories: group A, no AVN; group B, less than 25% involvement of the weight-bearing portion of the femoral head; group C, 25%–50% involvement; and group D, &gt;50% involvement. Histologic evidence of AVN was found in all 34 hips. Collapse occurred in none of the hips in groups A and B (n = 12), in 3 of 7 hips (43%) in group C, and in 13 of 15 hips (87%) in group D.</td>

<td>Observational-Dx</td>
<td>24 patients</td>
<td>To establish the reliability of 4 MRI parameters: extent of epiphyseal necrosis, lateral extrusion of the femoral head, physeal involvement, and metaphyseal changes.</td>
<td>An interobserver blind analysis was made to establish the reliability of 4 MRI parameters: extent of epiphyseal necrosis, lateral extrusion of the femoral head, physeal involvement, and metaphyseal changes. The interobserver analysis resulted in a good reliability for all MRI parameters (concordance, &gt;80%; K index, &gt;0.45). A statistical correlation study (Spearman test) was then done between each MRI parameter and the condition of the hips at follow-up evaluated by Stulberg class and a personal scored system (total score) of clinical-radiographic condition. All MRI parameters appeared well correlated to the Stulberg class and to the total score (S &gt;0.66; P&lt;0.05). Physeal involvement resulted the strongest correlated parameter (S = 0.84 for Stulberg class; S = 0.91 for total score).</td>

<td>67. Yoo WJ, Kim YJ, Menezes NM, Cheon JE, Jaramillo D.</td>
<td>Observational-Dx</td>
<td>17 children</td>
<td>To determine whether (1) there would be any age-related diffusion changes; (2) diffusion-weighted MRI would reveal ischemic damage; and (3) diffusion changes are correlated with prognostic MR findings in patients with Legg-Calve-Perthes disease.</td>
<td>Normal diffusion decreased with age. In Legg-Calve-Perthes disease hips, epiphyseal diffusion increased early and remained elevated through the healing stage. 6/17 patients who had a metaphyseal ADC greater than 50% over the normal side had 13 times greater odds of having an association with transphyseal reperfusion to the epiphysis. The increase of metaphyseal ADC also was associated with an increased T2-signal intensity in the metaphysis and presence of focal physeal irregularity.</td>

### Evidence Table Key

### Study Quality Category Definitions

- **Category 1**  The study is well-designed and accounts for common biases.
- **Category 2**  The study is moderately well-designed and accounts for most common biases.
- **Category 3**  There are important study design limitations.
- **Category 4**  The study is not useful as primary evidence. The article may not be a clinical study or the study design is invalid, or conclusions are based on expert consensus. For example:
  a) the study does not meet the criteria for or is not a hypothesis-based clinical study (e.g., a book chapter or case report or case series description);
  b) the study may synthesize and draw conclusions about several studies such as a literature review article or book chapter but is not primary evidence;
  c) the study is an expert opinion or consensus document.
- **M** = Meta-analysis

### Abbreviations Key

- ADC = Apparent diffusion coefficient
- AUC = Area under the curve
- AVN = Avascular necrosis
- CI = Confidence interval
- CT = Computed tomography
- ESWT = Extracorporeal shockwave therapy
- MDP = Methylene diophosphate
- MRI = Magnetic resonance imaging
- OA = Osteoarthritis
- ONFH = Osteonecrosis of the femoral head
- SPECT = Single-photon-emission computed tomography
- THA = Total hip arthroplasty
- TOH = Transient osteoporosis of the hip

Dx = Diagnostic
Tx = Treatment
