<td>3. Theumann NH, Etechami G, Duvoisin B, et al. Association between extrinsic and intrinsic carpal ligament injuries at MR arthrography and carpal instability at radiography: initial observations. Radiology. 2006;238(3):950-957.</td>
<td>Observational-Dx</td>
<td>72 patients with post-traumatic wrist pain 2 observers</td>
<td>To retrospectively compare the presence or absence of carpal instability on radiographs with the findings of magnetic resonance (MR) arthographic evaluation of intrinsic and extrinsic ligament tears in patients with chronic wrist pain.</td>
<td>Twenty-five triangular fibrocartilage complex, 18 (five partial, 13 complete) scapholunate ligament, and 25 (10 partial, 15 complete) lunotriquetral ligament tears were visualized. Twenty-two (all complete) extrinsic ligament tears were detected: two radial collateral ligament, 10 radioscaphocapitate ligament, and 10 radiolunotriquetral ligament tears. Interobserver agreement regarding intrinsic and extrinsic ligament tear detection at MR arthrography was excellent (kappa = 0.80). Nineteen patients had evidence of carpal instability on radiographs. Fourteen (52%) of 27 patients with at least one complete intrinsic lesion had no sign of carpal instability. On the other hand, the association of scapholunate ligament and/or lunotriquetral ligament and extrinsic ligament tears was significantly correlated (P &lt; .001) with carpal instability at radiography. The presence or absence of carpal instability on radiographs depends on the association between intrinsic and extrinsic ligament tears—even partial ones—rather than on the presence of intrinsic ligament tears alone, even when the tears are complete.</td>

<tr>
<td>7. Smith TO, Drew BT, Toms AP, Chojnowski AJ. The diagnostic accuracy of X-ray arthrography for triangular fibrocartilaginous complex injury: a systematic review and meta-analysis. J Hand Surg Eur Vol. 2012;37(9):879-887.</td>
<td>Meta-analysis</td>
<td>12 studies, 430 patients</td>
<td>To evaluate the diagnostic test accuracy of X-ray arthrography in the detection of TFCC tear.</td>
<td>X-ray arthrography presented with a pooled sensitivity of 76.2% and specificity of 92.5% for the detection of complete TFCC tear. The triple-compartment injection X-ray arthrography was superior to the single-compartment injection technique.</td>
<td>M</td>
</tr>
<tr>
<td>8. Lee RK, Ng AW, Tong CS, et al. Intrinsic ligament and triangular fibrocartilage complex tears of the wrist: comparison of MDCT arthrography, conventional 3-T MRI, and MR arthrography. Skeletal Radiol. 2013;42(9):1277-1285.</td>
<td>Observational-Dx</td>
<td>5 cadavers; 10 wrists</td>
<td>To compare the diagnostic performance of multidetector CT arthrography (CTA), conventional 3-T MR and MR arthrography (MRA) in detecting intrinsic ligament and triangular fibrocartilage complex (TFCC) tears of the wrist. Intravenous contrast was administered.</td>
<td>Sensitivities/specificity/accuracy of CTA, conventional MRI, and MRA were 100%/100%/100%, 66%/86%/80%, 100%/86%/90% for the detection of SLL tear, 100%/80%/90%, 60%/80%/70%, 100%/80%/90% for the detection of LTL tear, and 100%/100%/100%, 100%/86%/90%, 100%/100%/100% for the detection of TFCC tear. Overall CTA had the highest sensitivity, specificity, and accuracy among the three investigations while MRA performed better than conventional MR. CTA also had the highest sensitivity, specificity, and accuracy for identifying which component of the SLL and LTL was torn. Membranous tears of both SLL and LTL were better visualized than dorsal or volar tears on all three imaging modalities.</td>
<td>3</td>
</tr>
<tr>
<td>9. Kocharian A, Adkins MC, Amrami KK, et al. Wrist: improved MR imaging with optimized transmit-receive coil design. Radiology. 2002;223(3):870-876.</td>
<td>Observational-Dx</td>
<td>6 volunteers</td>
<td>To design and evaluate an optimized birdcage transmit-receive coil for the wrist that can provide higher SNR and higher uniformity compared with those with the same-sized PACs.</td>
<td>Blinded review of wrist images obtained in six volunteers showed that the optimized birdcage coil was preferred in 75% of the comparisons. An optimized birdcage coil designed for wrist imaging has improved both SNR and uniformity compared with those with a phased-array coil with the same geometry.</td>

<td>14. De Filippo M, Pogliacomi F, Bertellini A, et al. MDCT arthrography of the wrist: diagnostic accuracy and indications. Eur J Radiol. 2010;74(1):221-225.</td>
<td>Observational-Dx</td>
<td>44 wrists</td>
<td>To evaluate the diagnostic accuracy and indications of arthrography with Multidetector Computed Tomography (arthro-MDCT) of the wrist in patients with absolute or relative contraindications to magnetic resonance imaging (MRI) studies and in patients with periarticular metal implants using diagnostic arthroscopy as the gold standard.</td>
<td>In non-operated and operated wrists the comparison between arthro-MDCT and arthroscopy showed sensitivity, specificity and accuracy ranging between 92% and 94% for triangular fibrocartilage complex (TFCC), between 80% and 100% for intrinsic ligaments located within the proximal carpal compartment, and between 94% and 100% for articular cartilage. Inter-observer agreement between two radiologists, in the evaluation of all types of lesions, was almost perfect (k=0.96) and statistically significant (p&lt;0.05). Arthro-MDCT of the wrist provides an accurate diagnosis to identify chondral, fibrocartilaginous and intra-articular ligament lesions in patients who cannot be evaluated by MRI, and in post-surgical patients.</td>
<td>3</td>
</tr>
<tr>
<td>15. Moser T, Dosch JC, Moussaoui A, Buy X, Gangi A, Dietemann JL. Multidetector CT arthrography of the wrist joint: how to do it. Radiographics. 2008;28(3):787-800; quiz 911.</td>
<td>Review/Other-Dx</td>
<td>N/A</td>
<td>Review use of MDCT arthrography of the wrist joint.</td>
<td>MDCT arthrography is useful in the diagnosis and evaluation of different articular disorders. Main limitation is in evaluation of soft-tissue abnormalities; addition of US or MRI might help.</td>
<td>4</td>
</tr>
<tr>
<td>16. Schmid MR, Schertler T, Pfirrmann CW, et al. Interosseous ligament tears of the wrist: comparison of multi-detector row CT arthrography and MR imaging. Radiology. 2005;237(3):1008-1013.</td>
<td>Observational-Dx</td>
<td>8 patients; 9 cadavers</td>
<td>Comparison of CT arthrography (3 compartment injection) vs unenhanced MRI for intrinsic ligament tears (three segments of SL and LT ligaments) in cadavers, with subsequent direct anatomic correlation.</td>
<td>CT arthrography is superior to (more sensitive than) MRI for dorsal segment tears, with more equivalent performance for palmar and central tears; for all segments of both ligaments, interobserver agreement is much better for CT arthrography than MRI.</td>
<td>2</td>
</tr>
<tr>
<td>17. Teefey SA, Dahiya N, Middleton WD, Gelberman RH, Boyer MI. Ganglia of the hand and wrist: a sonographic analysis. AJR Am J Roentgenol. 2008;191(3):716-720.</td>
<td>Meta-analysis</td>
<td>55 patients 60 ganglia</td>
<td>Retrospective study to analyze the US appearance of ganglia of the hand and wrist.</td>
<td>34/60 ganglia were complex; 91% were located within the dorsal or volar wrist; 97% had well-defined margins; 76%, locules; 68% acoustic enhancement; 47% a thick wall; 15% internal reflectors; and 12% blood flow. Of the 23 simple ganglia, 11 involved the extensor or flexor tendon sheath, 73% of which were simple. Study showed that most ganglia are complex rather than simple on US.</td>

<td>18. Choi SJ, Ahn JH, Lee YJ, et al. de Quervain disease: US identification of anatomic variations in the first extensor compartment with an emphasis on subcompartmentalization. Radiology. 2011;260(2):480-486.</td>
<td>Observational-Dx</td>
<td>13 patients; 15 wrists</td>
<td>To demonstrate the usefulness of ultrasonography (US) in the detection of anatomic variations in the first extensor compartment of the wrist in patients with de Quervain disease</td>
<td>Subcompartmentalization within the first extensor compartment was observed during surgery in 11 of the 15 wrists (73%), including four (27%) that had subcompartmentalization only in the distal portion of this compartment. US was used to identify all 11 wrists showing subcompartmentalization within this compartment (sensitivity, 100%; 95% confidence interval [CI]: 74%, 100%), as well as three of the four wrists with distal incomplete subcompartmentalization. There was one wrist with false-positive distal incomplete subcompartmentalization. US had a positive predictive value in the detection of subcompartmentalization of 73% (95% CI: 47%, 91%). The number of tendon slips in this compartment detected with US was identical to that identified at surgery with one exception. US can be used to depict various types of anatomic variations in the first extensor compartment in patients with de Quervain disease.</td>

<tr>
<td>21. Descatha A, Huard L, Aubert F, Barbato B, Gorand O, Chastang JF. Meta-analysis on the performance of sonography for the diagnosis of carpal tunnel syndrome. Semin Arthritis Rheum. 2012;41(6):914-922.</td>
<td>Meta-analysis</td>
<td>13 studies</td>
<td>To review and pool recent large methodological studies evaluating the diagnosis performance of ultrasonography vs electrodiagnostic testing (EDX)</td>
<td>Among the 189 articles found, 13 articles were included. A cross-sectional area of the median nerve between 9.5 and 10.5 mm(2) (study included once only), found for 11 studies, gave the pooled sensitivity as 0.84 [0.81 to 0.87] and the likelihood ratio for a negative test as 0.21 [0.17 to 0.27]. Specificity (0.78 [0.69-0.88]) and the likelihood ratio for a positive test (3.74 [2.30-6.10]) were heterogeneous. For a threshold at 7.0 to 8.5 mm(2), pooled sensitivity was 0.94 [0.87 to 1.00], and for 11.5 to 13.0 mm(2) specificity was 0.97 [0.91 to 1.00]. The only significant variable on potential sources of heterogeneity was the cross-sectional area of the median nerve threshold and area under the curve was 0.87 (asymmetric).</td>

<td>30. Dohn UM, Ejbjerg BJ, Hasselquist M, et al. Detection of bone erosions in rheumatoid arthritis wrist joints with magnetic resonance imaging, computed tomography and radiography. Arthritis Res Ther. 2008;10(1):R25.</td>
<td>Observational-Dx</td>
<td>17 patients and 4 controls</td>
<td>To determine the performance of magnetic resonance imaging (MRI) and radiography for the detection of bone erosions in rheumatoid arthritis wrist bones, and to test whether measuring volumes of erosions on CT and MRI is reproducible and correlated to semiquantitative assessments (scores) of erosions on CT, MRI and radiography.</td>
<td>With CT as the reference method, the overall sensitivity, specificity and accuracy (concordance) of MRI for detecting erosions were 61%, 93% and 77%, respectively, while the respective values were 24%, 99% and 63% for radiography. The intramodality agreements when measuring erosion volumes were high for both CT and MRI (Spearman correlation coefficients 0.92 and 0.90 (both P &lt; 0.01), respectively). Correlations between volumes and scores of individual erosions were 0.96 for CT and 0.99 for MRI, while they were 0.83 (CT) and 0.80 (MRI) for persons' total erosion volume and total score (all P &lt; 0.01). MRI showed moderate sensitivity and good specificity and accuracy for detection of erosions in rheumatoid arthritis and healthy wrist bones, while radiography showed very low sensitivity. The tested volumetric method was highly reproducible and correlated to scores of erosions.</td>
<td>1</td>
</tr>
<tr>
<td>31. Duer-Jensen A, Ejbjerg B, Albrecht-Beste E, et al. Does low-field dedicated extremity MRI (E-MRI) reliably detect bone erosions in rheumatoid arthritis? A comparison of two different E-MRI units and conventional radiography with high-resolution CT scanning. Ann Rheum Dis. 2009;68(8):1296-1302.</td>
<td>Observational-Dx</td>
<td>20 patients and 5 healthy controls</td>
<td>To compare the ability of two different E-MRI units and conventional radiography (CR) to identify bone erosions in rheumatoid arthritis (RA) metacarpophalangeal (MCP) and wrist joints with CT scanning as the standard reference method.</td>
<td>The sensitivity of the Artoscan for detecting erosions was higher than that of the MagneVu and CR (MCP joints: 0.68, 0.54 and 0.57, respectively; wrists: 0.50, 0.23 and 0.29). Corresponding specificities for detecting erosions were 0.94, 0.93 and 0.99, respectively, in the MCP joints and 0.92, 0.98 and 0.98 in the wrist. The MagneVu allowed visualisation of 1.5 cm of the ventral-dorsal diameter of the bone. In the wrist, 31.6% of bones were visualised entirely and 37.9% of bones were 67-99% visualised. In MCP joints, 84.2% of bones were visualised entirely and 15.8% of bones were 67-99% visualised. With CT as the reference method for detecting erosions in RA hands, the Artoscan showed higher sensitivity than the MagneVu and CR. All imaging modalities had high specificities. The better performance of the Artoscan should be considered when selecting an imaging method in RA.</td>

<td>Experimental-Dx</td>
<td>219 total patients</td>
<td>To identify predictors of radiographic progression in a 2-year randomised, double-blind, clinical study (CIMESTRA) of patients with early rheumatoid arthritis (RA).</td>
<td>Baseline values: median DAS28 5.6 (range 2.4-8.0); anti-CCP positive 61%; radiographic erosions 56%. At 2 years: DAS28 2.0 (0.5-5.7), in DAS remission: 56%, radiographic progression 26% (wrist+MCP group, similar for wrist-only group). MRI bone oedema score was the only independent predictor of delta-TSS (wrist+MCP group: coefficient = 0.75 (95% CI 0.55 to 0.94), p&lt;0.001; wrist-only group: coefficient = 0.59 (95% CI 0.40 to 0.77), p&lt;0.001). Bone oedema score explained 41% of the variation in the progression of TSS (wrist+MCP group), 25% in wrist-only group (Pearson's r = 0.64 and r = 0.50, respectively). Results were confirmed by sensitivity analyses. In a randomised controlled trial aiming at remission in patients with early RA, baseline RAMRIS MRI bone oedema score of MCP and wrist joints (and of wrist only) was the strongest independent predictor of radiographic progression in hands, wrists and forefeet after 2 years. MRI synovitis score, MRI erosion score, DAS28, anti-CCP, SE, smoking, age and gender were not independent risk factors.</td>

<td>34. Zheng S, Robinson E, Yeoman S, et al. MRI bone oedema predicts eight year tendon function at the wrist but not the requirement for orthopaedic surgery in rheumatoid arthritis. Ann Rheum Dis. 2006;65(5):607-611.</td>
<td>Observational-Dx</td>
<td>42 total patients</td>
<td>To investigate the role of early magnetic resonance imaging (MRI) of the wrist in predicting functional outcome in rheumatoid arthritis.</td>
<td>At 8 years, tendon function was highly correlated with hand function (Sollerman score, $R = -0.51$, $p = 0.005$) and global function (health assessment questionnaire score, $R = 0.53$, $p = 0.004$). Using a model incorporating baseline and 1 year MRI scores, the MRI bone oedema score was strongly predictive of tendon function at 8 years ($\chi^2(2) = 15.3$, $p = 0.0005$), as was the MRI bone erosion score ($\chi^2(2) = 9.23$, $p = 0.01$). Hand function was also predicted by the baseline MRI erosion score ($p = 0.02$). MRI variables did not predict the requirement for surgery, but patients who had surgery were more likely to show progression of MRI bone erosion scores between baseline and 1 year ($p = 0.008$). Extensive MRI bone oedema and erosions at the wrist in early rheumatoid arthritis predict tendon dysfunction and impaired hand function in the medium term but not the requirement for joint or tendon surgery.</td>

<td>37. Anderson ML, Skinner JA, Felmlee JP, Berger RA, Amrami KK. Diagnostic comparison of 1.5 Tesla and 3.0 Tesla preoperative MRI of the wrist in patients with ulnar-sided wrist pain. J Hand Surg Am. 2008;33(7):1153-1159.</td>
<td>Observational-Dx</td>
<td>102 patients</td>
<td>To evaluate the diagnostic comparison of 1.5 Tesla and 3.0 Tesla preoperative MRI of the wrist in patients with ulnar-sided wrist pain.</td>
<td>A tear of the TFCC was identified retrospectively on 1.5T images in 49 of 58 patients and on 3.0T images in 15 of 16 patients. Compared with the gold standard of arthroscopy, 1.5T wrist MRI in this patient population had a sensitivity of 85%, a specificity of 75%, and an accuracy of 83% for reader 1 for the detection of a tear of the TFCC. In the same patient population, 3.0T wrist MRI had a sensitivity of 94%, a specificity of 88%, and an accuracy of 91% for reader 1. For reader 2, the improvement in sensitivity for the lunotriquetral ligament between the 1.5T and 3.0T images was statistically significant. The sensitivity, specificity, and accuracy of 3.0T wrist MRI for the TFCC is consistently higher compared with those of 1.5T wrist MRI. The trend suggests that 3.0T wrist MRI provides improved capability for detection of TFCC injuries. Given the available sample size, however, the confidence intervals around the point estimates are wide and overlapping. Further studies are needed to confirm or refute our results of the estimated sensitivity, specificity, and accuracy parameters.</td>

<td>43. Scheck RJ, Kubitzek C, Hierner R, et al. The scapholunate interosseous ligament in MR arthrography of the wrist: correlation with non-enhanced MRI and wrist arthroscopy. Skeletal Radiol. 1997;26(5):263-271.</td>
<td>Observational-Dx</td>
<td>41 patients</td>
<td>To compare three-compartment MR wrist arthrography with non-enhanced MRI in correlation with wrist arthroscopy, and to evaluate the potential of MR arthrography for consistently visualizing all parts of the scapholunate interosseous ligament of the wrist (SLIL) and exactly diagnosing the site and extent of SLIL defects.</td>
<td>Demonstration of SLIL defects was possible with high diagnostic confidence in 42% of SLIL segments by non-enhanced MRI and in 94% by MR arthrography. With wrist arthroscopy as the standard of reference, sensitivity and specificity values for SLIL perforations were 52%/34% for non-enhanced MRI and 90%/87% for MR arthrography. MR arthrography, using three-dimensional volume acquisition with thin slices (0.6-1.0 mm), combines the advantages of three-compartment arthrography and non-enhanced MRI. It shows the precise location and magnitude of ligamentous defects of all parts of the SLIL, correlates well with wrist arthroscopy and has potential implications for diagnosis and treatment planning.</td>

<td>Observational-Dx</td>
<td>31 patients; 40 wrists, 37 asymptomatic volunteers, 63 wrists</td>
<td>To examine the most adequate cut-off point for median nerve cross-sectional area and additional ultrasound features supporting the diagnosis of carpal tunnel syndrome (CTS).</td>
<td>In CTS the median nerve cross-sectional area was increased compared with the control group. Median nerve cross-sectional area of 10 mm² (DT) and 9 mm² (IT) had high sensitivity (85% and 88.5%, respectively), specificity (92.1% and 82.5%) and accuracy (89.3% and 82.5%) in the diagnosis of CTS. CTS patients had an increased carpal tunnel AP diameter, flexor retinaculum thickening, reduced median nerve mobility and decreased median nerve echogenicity. Ultrasound assists in the diagnosis of CTS using the median nerve diameter cut-off point of 10 mm² (DT) and 9 mm² (IT) and several additional findings.</td>

<td>65. Akcar N, Ozkan S, Mehmetoglu O, Calisir C, Adapinar B. Value of power Doppler and gray-scale US in the diagnosis of carpal tunnel syndrome: contribution of cross-sectional area just before the tunnel inlet as compared with the cross-sectional area at the tunnel. Korean J Radiol. 2010;11(6):632-639.</td>
<td>Observational-Dx</td>
<td>42 patients</td>
<td>To determine the value of gray-scale and power Doppler ultrasonography in the evaluation of carpal tunnel syndrome (CTS).</td>
<td>A statistically significant difference was found between patients and the control group for mean CSAb, area difference, percentage area increase, and flattening ratio (p &lt; 0.001, p &lt; 0.001, p &lt; 0.001, p &lt; 0.05, respectively). From the ROC curve we obtained optimal cut-off values of 11 mm(2) for CSAb, 3.65 for area difference, 50% for the percentage of area increase, and 2.6 for the flattening ratio. The mean number of vessels obtained by power Doppler ultrasonography from the median nerve was 1.2. We could not detect vessels from healthy volunteers. Mean CSAbs related to vascularity intensity scores were as follows: score 0: 12.3 +/- 2.8 mm(2), score 1: 12.3 +/- 3.1 mm(2), score 2: 14.95 +/- 3.5 mm(2), score 3: 19.3 +/- 3.8 mm(2). The mean PI value in vessels of the median nerve was 4.1 +/- 1. Gray-scale and power Doppler ultrasonography are useful in the evaluation of CTS.</td>

<td>Observational-Dx</td>
<td>151 patients, 206 wrists</td>
<td>To retrospectively assess the accuracy of gray-scale and color Doppler sonography in the diagnosis of carpal tunnel syndrome.</td>
<td>Carpal tunnel syndrome was confirmed in 172 wrists at nerve conduction studies. A median nerve cross-sectional area of at least 0.11 cm2 was calculated as a definition of median nerve swelling. In comparison with nerve conduction studies, nerve swelling showed the highest accuracy (91%) among gray-scale sonography criteria, and the presence of intraneural hypervascularization showed the highest accuracy (95%) among all sonography criteria. Logistic regression analysis showed that nerve hypervascularization was the only variable that independently predicted median nerve entrapment (odds ratio, 16.4; 95% confidence interval, 8.7-31.1; p &lt;0.001). Color Doppler sonography is more accurate than gray-scale sonography for characterizing median nerve involvement in patients with suspected carpal tunnel syndrome.</td>

<td>67. Rempel D, Evanoff B, Amadio PC, et al. Consensus criteria for the classification of carpal tunnel syndrome in epidemiologic studies. Am J Public Health. 1998;88(10):1447-1451.</td>
<td>Review/Other-Dx</td>
<td>N/A</td>
<td>Group of research physicians met with a goal of defining and ranking consensus criteria for the classification of carpal tunnel syndrome in epidemiologic studies.</td>
<td>Agreement reached by group: First, no perfect gold standard exists for carpal tunnel syndrome. Combination of electrodiagnostic study findings and symptom characteristics will provide the most accurate information for classification of carpal tunnel syndrome. Second, use of only electrodiagnostic study findings is not recommended. Finally, in the absence of electrodiagnostic studies, specific combinations of symptom characteristics and physical examination findings may be useful in some settings but are likely to result in greater misclassification of disease status.</td>

<td>68. Martins RS, Siqueira MG, Simplicio H, Agapito D, Medeiros M. Magnetic resonance imaging of idiopathic carpal tunnel syndrome: correlation with clinical findings and electrophysiological investigation. Clin Neurol Neurosurg. 2008;110(1):38-45.</td>
<td>Observational-Dx</td>
<td>74 patients</td>
<td>To compare clinical evaluation, electrophysiological investigation and magnetic resonance findings in assessing the severity of idiopathic carpal tunnel syndrome.</td>
<td>Cross-sectional area of median nerve was smaller at hamate level than at radio-ulnar joint and pisiform levels (p&lt;0.001). With exception of median nerve area at hamate level, there was a lower degree of correlation between MRI parameters and findings obtained by clinical assessments and electrophysiological measurements. The median nerve area at hamate level correlated negatively with duration of symptoms, two-point discrimination, symptoms severity score and positively with sensory nerve conduction velocity (p&lt;0.01). In patients with idiopathic carpal tunnel syndrome, median nerve area measured by wrist magnetic resonance at hamate level may be considered as a valuable indicator to grading the severity of disease.</td>

<td>Observational-Dx</td>
<td>120 patients</td>
<td>Prospective enrollment of patients with carpal tunnel syndrome to compare the value of MRI with electrodiagnostic studies for: 1) prediction of 1-year outcomes and 2) identification of patients who are likely to benefit from surgical treatment.</td>
<td>The authors recontacted 105 of 120 participants at 12 months. Of these, 30 patients had had surgery and 75 had not. Patients who had undergone surgery showed greater improvement at 1 year than those who had not had surgery. The length of the abnormal T2-weighted nerve signal on MRI and median-ulnar sensory latency difference were the strongest predictors of surgical benefit. Findings obtained with MRI of the carpal tunnel predict surgical benefit independently of nerve conduction studies.</td>

ACR Appropriateness Criteria®

Evidence Table Key

Study Quality Category Definitions

- **Category 1**: The study is well-designed and accounts for common biases.
- **Category 2**: The study is moderately well-designed and accounts for most common biases.
- **Category 3**: There are important study design limitations.
- **Category 4**: The study is not useful as primary evidence. The article may not be a clinical study or the study design is invalid, or conclusions are based on expert consensus. For example:
  a) the study does not meet the criteria for or is not a hypothesis-based clinical study (e.g., a book chapter or case report or case series description);
  b) the study may synthesize and draw conclusions about several studies such as a literature review article or book chapter but is not primary evidence;
  c) the study is an expert opinion or consensus document.
- **M = Meta-analysis**

Dx = Diagnostic

Tx = Treatment
