<td>Observational-Dx</td>
<td>134 patients</td>
<td>To determine the diagnostic value of dRBC.</td>
<td>The cause of hematuria was proven in 68 patients (35% glomerular; 65% nonglomerular). Patients with glomerular disease had significantly more albuminuria and dRBC than patients with nonglomerular disease, but the %dRBC ranged from 1 to 50% and no optimal cutoff could be identified. Logistic regression analysis showed that %dRBC had a predicted probability to diagnose glomerular disease of 77.9% (area under the curve, AUC, 0.85). When %dRBC was combined with other risk factors such as serum creatinine, sex, age, dipstick erythrocyte or proteinuria score and number of casts, the predictive probability increased to 90.6% (AUC 0.97). Follow-up of the included patients showed no benefit of dRBC to identify patients at risk for glomerular disease. The diagnostic value of routinely collected urinary dRBC to diagnose glomerular disease in patients presenting with hematuria is modest. However, including dRBC with other variables, such as age and erythrocyte score on dipstick testing may increase the sensitivity, but needs to be confirmed in another, preferably larger, population.</td>

<td>Review/Other-Dx</td>
<td>300 patients</td>
<td>To describe patients with normal renal function for evaluation of hematuria, usually microscopic, in whom prior urologic and radiological studies had failed to determine the cause of bleeding.</td>
<td>Urinary sediment from the patients and first-degree relatives revealed hemoglobin and red blood cell casts; the inheritance pattern was consistent with autosomal dominant transmission. During follow-up for up to 18 years, renal function remained normal, thus confirming the diagnosis of benign familial hematuria. Immunoglobulin A nephropathy and Alport's syndrome were less common than benign familial hematuria and could be differentiated from it by history, physical examination, and routine laboratory testing. Since benign familial hematuria is a common disorder in adults with hematuria and normal renal function, urinary sediment from patients and family members should be examined before extensive urologic and radiological procedures are performed.</td>

<td>Review/Ot her-Dx</td>
<td>121 patients</td>
<td>To correlate the clinical and laboratory findings with increased renal cortical echogenicity in children with acute renal diseases.</td>
<td>There were 7 newborns and 114 children (67 male, 47 female) with increased renal cortical echogenicity with a mean (+/-SD) age of 7.0 (+/-4.4) years. The clinical diagnosis was anatomic abnormality (including vesicoureteral reflux, ureteropelvic junction obstruction, ureterovesical junction obstruction, double collecting system) in 9%, urinary tract infection in 21%, urolithiasis in 6%, nephrotic syndrome in 20%, glomerulonephritis in 32%, and other diseases in 12%. Hyperechogenicity was bilateral in 72%, right-sided in 19%, and left-sided in 9%. There were 81 patients in group 1 and 33 patients in group 2 (grade II, 29; grade III, 4). There was no statistically significant difference between the groups with regard to age, sex, and serum blood urea nitrogen level, serum creatinine level, uric acid level, urine pH, and specific gravity. Hematuria was more frequent in group 2, whereas proteinuria and pyuria incidences were similar in the 2 groups. In patients with hematuria, glomerulonephritis was the most common cause.</td>

<td>Review/Ot her-Dx</td>
<td>187 studies/736 patients</td>
<td>To conduct a systematic review of the literature for micro- and macroscopic hematuria cause by renal vein entrapment</td>
<td>We identified 187 published reports/studies that covered 736 patients, of whom 288 had microscopic hematuria and 448 had macroscopic hematuria. The patient cohort comprised 159 patients aged &lt;/=17 years. Abdominal pain was absent in approximately 65% of all patients, and a clinically relevant left-sided varicocele was observed in 29% of the male patients. A normal pre-aortic left renal vein and an anomalous anatomy were noted in 680 and 56 patients, respectively. The body mass index (BMI) was lower in patients with renal vein entrapment than in the controls, with a regression of hematuria correlating with an increase in BMI. A surgical procedure was attempted in 34% of the patients, of which the most common were endovascular stenting and transposition of the renal vein distally into the vena cava.</td>

<td>42. Polito C, La Manna A, Signoriello G, Marte A. Recurrent abdominal pain in childhood urolithiasis. Pediatrics. 2009; 124(6):e1088-1094.</td>
<td>Observational-Dx</td>
<td>100 consecutive patients 250 controls</td>
<td>To establish the clinical presentation and features of pain attacks in children with recurrent abdominal pain (RAP) and urolithiasis.</td>
<td>Fifty-three patients had no history of dysuria or gross hematuria, and only 35 had hematuria at the first visit; 41 patients were evaluated for urolithiasis only because of a family history of kidney stones associated with RAP. Twenty-nine patients had been previously hospitalized for abdominal symptoms. Sixteen patients and 4 control subjects (1.5%) had undergone a previous appendectomy (P &lt; .0001). Two to 28 months before the diagnosis of urolithiasis, 37 patients underwent abdominal ultrasonography, which did not show urinary stones. Sixty-nine percent of subjects younger than 8 years of age had central/diffuse abdominal pain. The mean frequency of pain attacks was 4 to 9 times lower than in patients with functional or organic gastrointestinal RAP. Because of the inconstant occurrence of dysuria and hematuria, the location of pain in areas other than the flank, and the lack of calculi shown on imaging studies performed after pain attacks, the urologic origin of pain may be overlooked and ineffective procedures performed. The possibility of urolithiasis should be considered in children with RAP who have a family history of urolithiasis and/or infrequent pain attacks, even when dysuria and hematuria are lacking, and in younger children even when pain is not lateral.</td>

<td>43. Persaud AC, Stevenson MD, McMahon DR, Christopher NC. Pediatric urolithiasis: clinical predictors in the emergency department. Pediatrics. 2009; 124(3):888-894.</td>
<td>Review/Ot her-Dx</td>
<td>339 patients</td>
<td>To identify factors that predict the presence of urolithiasis detected with unenhanced computed tomography (UCT) in children.</td>
<td>Fifty-seven stones (51.8%) were ureteral, 26 (23.6%) were renal, and 4 (3.6%) were in the bladder. Among children who did not have a stone identified through UCT, 23 cases (10%) of potentially significant, alternative diagnoses were identified. A history of urolithiasis, a history of nausea and vomiting, the presence of flank pain on examination, and ≥2 red blood cells per high-power field in urine microscopy were positively associated with urolithiasis. A history of fever or dysuria and costovertebral angle tenderness on physical examination were inversely associated with urolithiasis on UCT scans. CONCLUSIONS: UCT plays an important role in the diagnostic evaluation of children with flank pain. Approximately 15% of children with urolithiasis do not have hematuria.</td>

<td>Observatio nal-Dx</td>
<td>162 children</td>
<td>To evaluate the clinical, radiological and metabolic features of children with urolithiasis or microlithiasis</td>
<td>The most frequently involved site was in the kidneys (86%). Ureters and bladder were involved in 12 and 2% of the cases, respectively. A family history of urolithiasis, presenting symptoms and underlying metabolic abnormalities were similar for microlithiasis and the patients with larger stones. However, in our study population, microlithiasis was mainly a disease of young infants, with a greater chance for remission and often not associated with structural changes. The presenting symptoms of urolithiasis show a wide spectrum, so that a high index of suspicion is important for early detection. A metabolic abnormality can be identified in 87% of cases of urolithiasis. Detection of microlithiasis may explain a number of symptoms, thus reducing invasive diagnostic procedures and allowing early recognition of metabolic abnormalities. These results draw attention to the importance of screening for UTIs in patients with urolithiasis.</td>

<td>Observatio nal-Dx</td>
<td>45 patients</td>
<td>To compare the diagnostic capabilities of standard- and reduced-dose CT in the detection of nephroureterolithiasis in children.</td>
<td>Compared with the standard tube current used for the original CT scans, there was no significant reduction (p=0.37) in detection of renal stones at the 80-mA setting (mean dose reduction, 67%; range, 43-81%); and at the 40-mA setting (mean dose reduction, 82%; range, 72-90%), the detection rate was significantly lower (p=0.05). At the 40-mA setting, there was no significant difference among the children weighing 50 kg or less (p=0.4). Detection of ureteral stones and hydronephrosis was not significantly different at 80 and 40 mA; however, disease frequency was low, and no definite conclusion can be made. Simulated dose reduction is a useful tool for determining diagnostic thresholds for MDCT detection of renal stones in children. Use of the 80-mA setting for all children and 40 mA for children weighing 50 kg or less does not significantly affect the diagnosis of pediatric renal stones.</td>

<td>Observational-Dx</td>
<td>25 patients</td>
<td>To evaluate the performance of CT examinations at 80 and 100 kV with tube current–time products of 75–150 mA and the effect of adaptive statistical iterative reconstruction (ASIR) on CT image quality in patients with urinary stone disease.</td>
<td>Modified-protocol filtered back projection (FBP) images showed low image quality (score, 2.5), with improvement on modified-protocol ASIR images (score, 3.4) (P = .03). All 33 stones (mean diameter, 6.1 mm; range, 2–28 mm) at modified-protocol CT were diagnosed by both readers. In 20 of 25 patients (80%), ASIR images were rated adequate for rendering other diagnoses in the abdomen (score, 2.0), as opposed to FBP images (score, 1.3). Mean radiation dose for modified-protocol CT was 1.8 mGy (1.3 mGy for patients &lt; 200 lb; 2.3 mGy for patients &gt; 200 lb) in comparison with 9.9 mGy for reference-protocol CT (P = .001). Image quality improvements with ASIR at reduced radiation dose of 1.8 mGy enabled effective evaluation of urinary calculi without substantially affecting diagnostic confidence.</td>

<td>Observational-Dx</td>
<td>67 patients with urinary stone 67 control</td>
<td>To determine the diagnostic value of color Doppler twinkling artifact in sites negative for stones on B-mode renal US.</td>
<td>Twinkling artifact was frequent in patients with stone disease (95.5%) compared to controls (9.0%) (P&lt;0.001). Twinkling artifact was highly associated to renal stone disease and present in renal areas where a stone was undetected with B-mode approach suggesting its diagnostic role although further studies are needed to confirm its accuracy.</td>
<td>3</td>
</tr>
<tr>
<td>61. Shabana W, Bude RO, Rubin JM.</td>
<td>Review/Other-Dx</td>
<td>7 uric acid calculi</td>
<td>To assess the ability of the color Doppler twinkling artifact to detect renal stones relative to acoustic shadowing</td>
<td>The contrast-to-noise ratios for twinkling were significantly higher than for acoustic shadowing. On average, twinkling produced 19.2 dB greater contrast-to-noise ratios for stones in the phantom and 17.6 dB more for the stones in the kidneys. In addition, ANOVA showed that twinkling is resistant to focusing and scanning frequency differences. The results suggest that the twinkling artifact is a robust method for detecting the presence of renal calculi. The color signature is easier to detect than is acoustic shadowing. Twinkling may be relatively resistant to many of the problems that plague US examinations for renal stones, i.e., out-of-focus scans that might be caused by beam aberration effects due to patient body habitus.</td>

<td>62. Dillman JR, Kappil M, Weadock WJ, et al. Sonographic twinkling artifact for renal calculus detection: correlation with CT. Radiology. 2011; 259(3):911-916.</td>
<td>Observational-Dx</td>
<td>1,828 US reports</td>
<td>To retrospectively correlate sonographic color Doppler twinkling artifact within the kidneys with unenhanced computed tomography (CT) in the detection of nephrolithiasis.</td>
<td>The presence of sonographic renal twinkling artifact, in general, had a 78% (95% confidence interval: 0.66, 0.90) positive predictive value for nephrolithiasis anywhere in the kidneys at CT. The true-positive rate of twinkling artifact for confirmed calculi at CT was 49% (73 of 148 twinkling foci), while the false-positive rate was 51% (75 of 148 twinkling foci). The overall sensitivity of twinkling artifact for the detection of specific individual renal calculi observed at CT was 55% (95% confidence interval: 0.47, 0.64). While renal twinkling artifact is commonly associated with nephrolithiasis, this finding is relatively insensitive in routine clinical practice and has a high false-positive rate when 5-mm unenhanced CT images are used as the reference standard.</td>

<td>64. Johnson EK, Faerber GJ, Roberts WW, et al. Are stone protocol computed tomography scans mandatory for children with suspected urinary calculi? Urology. 2011; 78(3):662-666.</td>
<td>Observational-Dx</td>
<td>42 patients</td>
<td>To examine the clinical utility of noncontrast-enhanced computed tomography (NCCT) in pediatric patients with urolithiasis who progressed to surgery. Although NCCT is routine for the evaluation of adult patients with suspected urolithiasis, its routine use in the pediatric population is tempered by concern about radiation exposure.</td>
<td>A discernible risk factor or cause of urolithiasis was absent in 21 patients (47%). A review of imaging studies found 38 with stones visible on ultrasonography and/or abdominal plain film. A total of 21 patients underwent NCCT, in addition to ultrasonography and/or abdominal plain film. Of these, only 5 patients required NCCT for the diagnosis or management of their stone. Nearly 90% of pediatric patients treated for symptomatic urolithiasis could have completed their evaluation and treatment without undergoing NCCT. For children who present with signs and symptoms suggesting urinary calculi, an initial evaluation and imaging with ultrasonography and abdominal plain film might suffice, avoiding the radiation of NCCT.</td>

<td>79. Raz O, Haifler M, Copel L, et al. Use of adult criteria for slice imaging may limit unnecessary radiation exposure in children presenting with hematuria and blunt abdominal trauma. Urology. 2011; 77(1):187-190.</td>
<td>Observational-Dx</td>
<td>46 consecutive patients</td>
<td>To examine whether it would be safe to use adult criteria for imaging in pediatric blunt renal trauma and hematuria.</td>
<td>The performance of the macro-microhematuria distinction in the prediction of renal injury on CT scan is relatively poor: sensitivity 59%, specificity 14%, positive predictive value (PPV) 84%, and negative predictive value (NPV) 62%, whereas the performance of macrohematuria criteria in the prediction of renal-relevant injury is sensitivity 100%, specificity 61%, PPV 18%, and NPV 93%. The yield of abdominal CT in pediatric renal trauma is low in patients presenting with microhematuria. Our data suggest that it may be possible that adult criteria for renal imaging are sufficient for children with abdominal blunt trauma and microhematuria. Adopting such strategy will result in substantial reduction in exposure to radiation, supposedly without increasing the patient's risk.</td>

<td>Observational-Dx</td>
<td>234 patients</td>
<td>Retrospective review was performed to determine the accuracy of CT cystography and the role of multiplanar reformation in the diagnosis of bladder injury.</td>
<td>From the total of 234 examinations, 216 (92.3%) were interpreted as negative and 18 examinations (7.7%) were interpreted as positive. On the 18 positive examinations, 11 were extraperitoneal bladder rupture, five were intraperitoneal bladder rupture, and two were combined intraperitoneal and extraperitoneal bladder rupture. Surgical bladder exploration and repair were performed in nine of the 18 cases. Seven (77.8%) of the nine cases had operative findings consistent with the CT cystogram findings. The overall sensitivity and specificity of CT cystography in diagnosing bladder rupture were each 100%. For extraperitoneal bladder rupture, the sensitivity and specificity were 92.8% and 100%, respectively. For intraperitoneal rupture, the sensitivity and specificity were 100% and 99%, respectively. CT cystography is accurate for diagnosing bladder rupture. Sagittal and coronal multiplanar reformations may be helpful in identifying most sites of bladder rupture.</td>

<td>92. Saad DF, Gow KW, Redd D, Rausbaum G, Wulkan ML.</td>
<td>Review/Ot her-Dx</td>
<td>1 case</td>
<td>To describe renal artery pseudoaneurysm secondary to blunt trauma treated with microcoil embolization.</td>
<td>An 11-year-old girl fell off a horse onto her right flank. She sustained multiple right hepatic lobe lacerations and a complex fracture of the upper pole of the right kidney. Her initial hospital course was uncomplicated, and she was discharged after an uneventful 6-day course. The child did well for 2 weeks, until she developed right back pain and gross hematuria. A computed tomography scan revealed a right renal artery pseudoaneurysm. Angiography confirmed the presence of a pseudoaneurysm, which was fed by a single segmental branch originating from the renal artery. The artery was successfully occluded with a single platinum microcoil, which was demonstrated by the absence of contrast flow into the pseudoaneurysm. The patient recovered and was discharged shortly after the procedure. She initially had intermittent pain and hematuria, which resolved. Follow-up computed tomography scans have shown resolution of both the renal and hepatic lesions.</td>

<td>94. Olthof DC, Joosse P, van der Vlies CH, de Reijke TM, Goslings JC. Routine urinalysis in patients with a blunt abdominal trauma mechanism is not valuable to detect urogenital injury. Emergency Medicine Journal. 32(2):119-23, 2015 Feb.</td>
<td>Review/Other-Dx</td>
<td>1815 patients</td>
<td>To investigate whether the routine performance of urinalysis in patients with a blunt trauma mechanism is still valuable.</td>
<td>A total of 1815 patients were included. The prevalence of intra-abdominal and urogenital injuries was 13% and 8%, respectively. In 1363 patients (75%), urinalysis was performed and 1031 patients (57%) underwent imaging for urogenital injury as well. The presence of macroscopic haematuria (n=16) led to clinical consequences in 73% of the patients (11 out of 15), regardless of the findings on imaging. Microscopic haematuria on urinalysis in combination with no findings on imaging led to clinical consequences in 8 out of 212 patients (4%). Microscopic haematuria on urinalysis in patients who did not have imaging for urogenital injury did not lead to clinical consequences (0 out of 54 patients; 0%). All the 8 patients who underwent an intervention had positive findings on imaging.</td>

<td>Holmes JF, Mao A, Awasthi S, McGahan JP, Wisner DH, Kuppermann N. Validation of a prediction rule for the identification of children with intra-abdominal injuries after blunt torso trauma. Ann Emerg Med. 2009; 54(4):528-533.</td>
<td>Observational-Dx</td>
<td>1,324 patients</td>
<td>To validate the accuracy of a previously derived clinical prediction rule for the identification of children with intra-abdominal injuries after blunt torso trauma.</td>
<td>The prediction rule had the following test characteristics: sensitivity=149 of 157, 94.9% (95% confidence interval [CI] 90.2% to 97.7%) and specificity=357 of 962, 37.1% (95% CI 34.0 to 40.3%). Three hundred sixty-five patients tested negative for the rule; thus, strict application would have resulted in a 33% reduction in abdominal CT scanning. Of the 8 patients with intra-abdominal injury not identified by the prediction rule, 1 underwent a laparotomy. This patient had a serosal tear and a mesenteric hematoma at laparotomy, neither of which required specific surgical intervention. A clinical prediction rule consisting of 6 variables, easily available to clinicians in the ED, identifies most but not all children with intra-abdominal injury. Application of the prediction rule to this sample would have reduced the number of unnecessary abdominal CT scans performed but would have failed to identify 1 child undergoing (a nontherapeutic) laparotomy. Thus, further refinement of this prediction rule in a large, multicenter cohort is necessary before widespread implementation.</td>

Evidence Table Key

Study Quality Category Definitions

- **Category 1** The study is well-designed and accounts for common biases.
- **Category 2** The study is moderately well-designed and accounts for most common biases.
- **Category 3** There are important study design limitations.
- **Category 4** The study is not useful as primary evidence. The article may not be a clinical study or the study design is invalid, or conclusions are based on expert consensus. For example:
  a. The study does not meet the criteria for or is not a hypothesis-based clinical study (e.g., a book chapter or case report or case series description);
  b. The study may synthesize and draw conclusions about several studies such as a literature review article or book chapter but is not primary evidence;
  c. The study is an expert opinion or consensus document.
- **Meta-analysis**
  a. *Good quality* – the study design, methods, analysis, and results are valid and the conclusion is supported.
  b. *Inadequate quality* – the study design, analysis, and results lack the methodological rigor to be considered a good meta-analysis study.
