<td>2. Roberts KB. Urinary tract infection: clinical practice guideline for the diagnosis and management of the initial UTI in febrile infants and children 2 to 24 months. <em>Pediatrics.</em> 2011;128(3):595-610.</td>
<td>Review/Other-Dx</td>
<td>N/A</td>
<td>To revise the American Academy of Pediatrics practice parameter regarding the diagnosis and management of initial UTIs in febrile infants and young children.</td>
<td>Diagnosis is made on the basis of the presence of both pyuria and at least 50,000 colonies per mL of a single uropathogenic organism in an appropriately collected specimen of urine. After 7 to 14 days of antimicrobial treatment, close clinical follow-up monitoring should be maintained to permit prompt diagnosis and treatment of recurrent infections. US of the kidneys and bladder should be performed to detect anatomic abnormalities. Data from the most recent 6 studies do not support the use of antimicrobial prophylaxis to prevent febrile recurrent UTI in infants without VUR or with grade I to IV VUR. Therefore, a VCUG is not recommended routinely after the first UTI; VCUG is indicated if renal and bladder US reveals hydronephrosis, scarring, or other findings that would suggest either high-grade VUR or obstructive uropathy and in other atypical or complex clinical circumstances. VCUG should also be performed if there is a recurrence of a febrile UTI. The recommendations in this guideline do not indicate an exclusive course of treatment or serve as a standard of care; variations may be appropriate. Recommendations about antimicrobial prophylaxis and implications for performance of VCUG are based on currently available evidence. As with all American Academy of Pediatrics clinical guidelines, the recommendations will be reviewed routinely and incorporate new evidence, such as data from the Randomized Intervention for Children With Vesicoureteral Reflux (RIVUR) study.</td>

<td>7. Ismaili K, Wissing KM, Lolin K, et al. Characteristics of first urinary tract infection with fever in children: a prospective clinical and imaging study. <em>Pediatr Infect Dis J.</em> 2011;30(5):371-374.</td>
<td>Observational-Dx</td>
<td>209 children</td>
<td>To provide the clinical characteristics, uropathogen frequencies, and antimicrobial resistance rates of first UTI diagnosed in febrile Belgian children. The ability of noninvasive US to detect renal abnormalities and VUR in these patients was also assessed.</td>
<td>Among these children, 63% were females and 37% were males, and 75% of them had their first UTI before the age of 2 years. The most common causative agent was Escherichia coli (91% of cases) with high rate resistance to ampicillin (58%) and trimethoprim/sulfamethoxazole (38%). Of these children, 25% had evidence of VUR (15 boys and 38 girls). VUR was of low grade in 85% of cases. The overall performance of renal US as a diagnostic test to detect significant uropathies excluding low-grade VUR was excellent; the sensitivity attained 97% and the specificity 94%. Girls represent 63% of cases with first UTI. For 91% of UTIs, Escherichia coli is held responsible with a high rate of resistance to ampicillin and trimethoprim/sulfamethoxazole. US is an excellent screening tool that allows avoidance of unjustified VCUG studies.</td>

<td>8. Keren R, Carpenter MA, Hoberman A, et al. Rationale and design issues of the Randomized Intervention for Children With Vescoureteral Reflux (RIVUR) study. <em>Pediatrics.</em> 2008;122 Suppl 5:S240-250.</td>
<td>Review/Other-Dx</td>
<td>600 children aged 2 to 72 months will be recruited</td>
<td>To determine if antimicrobial prophylaxis with trimethoprim/sulfamethoxazole prevents recurrent UTI and renal scarring in children who are found to have VUR after a first or second UTI in an ongoing RIVUR study.</td>
<td>The primary outcome is recurrence of UTI. Secondary outcomes include time to recurrent UTI, renal scarring (assessed by DMSA scan), treatment failure, renal function, resource utilization, and development of antimicrobial resistance in stool flora. The RIVUR study will provide useful information to clinicians about the risks and benefits of prophylactic antibiotics for children who are diagnosed with VUR after a first or second UTI. The data and specimens collected over the course of the study will allow researchers to better understand the pathophysiology of recurrent UTI and its sequelae.</td>

<tr>
<td>9. Montini G, Rigon L, Zucchetta P, et al. Prophylaxis after first febrile urinary tract infection in children? A multicenter, randomized, controlled, noninferiority trial. <em>Pediatrics.</em> 2008;122(5):1064-1071.</td>
<td>Experimental-Tx</td>
<td>338 children aged 2 months to &lt;7 years</td>
<td>Multicenter, open-label, randomized controlled multicenter trial to determine whether no prophylaxis is similar to antimicrobial prophylaxis for 12 months in reducing the recurrence of febrile UTI in children after a first febrile UTI.</td>
<td>Intention-to-treat analysis showed no significant differences in the primary outcome between no prophylaxis and prophylaxis: 12 (9.45%) of 127 vs 15 (7.11%) of 211. In the subgroup of children with reflux, the recurrence of febrile UTI was 9 (19.6%) of 46 on no prophylaxis and 10 (12.1%) of 82 on prophylaxis. No significant difference was found in the secondary outcome: 2 (1.9%) of 108 on no prophylaxis vs 2 (1.1%) of 187 on prophylaxis. Bivariate analysis and Cox proportional hazard model showed that grade III reflux was a risk factor for recurrent febrile UTIs. Whereas increasing age was protective, use of no prophylaxis was not a risk factor. For children with or without primary nonsevere reflux, prophylaxis does not reduce the rate of recurrent febrile UTIs after the first episode.</td>

<td>10. Pennesi M, Travan L, Peratoner L, et al. Is antibiotic prophylaxis in children with vesicoureteral reflux effective in preventing pyelonephritis and renal scars? A randomized, controlled trial. <em>Pediatrics.</em> 2008;121(6):e1489-1494.</td>
<td>Experimental-Tx</td>
<td>100 patients</td>
<td>Multicenter, open-label, randomized, controlled trial to assess the effectiveness of antibiotic prophylaxis in preventing recurrence of pyelonephritis and avoiding new scars in a sample of children who were younger than 30 months and VUR.</td>
<td>The baseline characteristics in the 2 study groups were similar. There were no differences in the risk for having at least 1 pyelonephritis episode between the intervention and control groups. At the end of follow-up, the presence of renal scars was the same in children with and without antibiotic prophylaxis. Continuous antibiotic prophylaxis was ineffective in reducing the rate of pyelonephritis recurrence and the incidence of renal damage in children who were younger than 30 months and had VUR grades II through IV.</td>
<td>1</td>
</tr>
<tr>
<td>11. Hodson EM, Wheeler DM, Vimalchandra D, Smith GH, Craig JC. Interventions for primary vesicoureteric reflux. <em>Cochrane Database Syst Rev.</em> 2007(3):CD001532.</td>
<td>Review/Other-Dx</td>
<td>11 studies 1,148 children</td>
<td>Meta-analysis was performed to evaluate the benefits and harms of different treatment options for primary VUR.</td>
<td>Risk of UTI by 2, 5 and 10 years was not significantly different between surgical and medical groups (2 years RR 1.07, 95% CI, 0.32 to 2.09; 5 years RR 0.99, 95% CI, 0.79 to 1.26; 10 years RR 1.06, 95% CI, 0.78 to 1.44). Combined treatment resulted in a 50% reduction in febrile UTI by 10 years (RR 0.54, 95% CI, 0.55 to 0.92) but no concomitant reduction in risk of new or progressive renal damage by 10 years (RR 1.03, 95% CI, 0.53 to 2.00). In 2 small studies no significant differences in risk for UTI (RR 0.75, 95% CI, 0.15 to 3.84) or renal damage (RR 1.70, 95% CI, 0.36 to 8.07) were found between antibiotic prophylaxis and no treatment. It is uncertain whether the treatment of children with VUR confers clinically important benefit. The additional benefit of surgery over antibiotics alone is small at best. Assuming a UTI rate of 20% for children with VUR on antibiotics for 5 years, 9 reimplantations would be required to prevent 1 febrile UTI, with no reduction in the number of children developing any UTI or renal damage.</td>

<td>12. Shaikh N, Ewing AL, Bhatnagar S, Hoberman A. Risk of renal scarring in children with a first urinary tract infection: a systematic review. <em>Pediatrics</em>. 2010;126(6):1084-1091.</td>
<td>Meta-analysis</td>
<td>33 studies</td>
<td>To review the prevalence of acute and chronic renal imaging abnormalities in children after an initial UTI.</td>
<td>Among children with an initial episode of UTI, 57% (95% CI: 50–64) had changes consistent with acute pyelonephritis on the acute-phase DMSA renal scan and 15% (95% CI: 11–18) had evidence of renal scarring on the follow-up DMSA scan. Children with VUR were significantly more likely to develop pyelonephritis (RR: 1.5 [95% CI: 1.1–1.9]) and renal scarring (RR: 2.6 [95% CI: 1.7–3.9]) compared with children with no VUR. Children with VUR grades III or higher were more likely to develop scarring than children with lower grades of VUR (RR: 2.1 [95% CI: 1.4–3.2]). The pooled prevalence values provided from this study provide a basis for an evidence-based approach to the management of children with this frequently occurring condition.</td>

<td>13. Ditchfield MR, De Campo JF, Cook DJ, et al. Vesicoureteral reflux: an accurate predictor of acute pyelonephritis in childhood urinary tract infection? <em>Radiology</em>. 1994;190(2):413-415.</td>
<td>Observational-Dx</td>
<td>150 consecutive patients; 300 kidneys</td>
<td>Prospective study to determine the association between VUR and the presence of acute pyelonephritis in children with UTI. All patients had renal cortical scintigraphy (with Tc-99m DMSA or Tc-99m gluconate) and VCUG to identify the presence of cortical defects and VUR, respectively.</td>
<td>Of 300 kidneys, 88 (29.3%) had a cortical defect at scintigraphy. 54/88 patients (61%) did not have VUR demonstrated at VCUG. Conversely, 72/300 kidneys (24%) had VUR; of these, 38 (53%) had no cortical defect. Sensitivity of VCUG in helping predict a defect was 38.6%, and the specificity was 82.1%. VUR (as shown by VCUG) and renal cortical scintigraphic defects frequently occur independently of each other. Renal cortical scintigraphy may be a more accurate predictor of patients at risk for scarring.</td>

<td>23. Rosenberg AR, Rossleigh MA, Brydon MP, Bass SJ, Leighton DM, Farnsworth RH. Evaluation of acute urinary tract infection in children by dimercaptosuccinic acid scintigraphy: a prospective study. <em>J Urol.</em> 1992;148(5 Pt 2):1746-1749.</td>
<td>Review/Other-Dx</td>
<td>65 children evaluated; 34 had abnormal DMSA scans</td>
<td>A prospective study examining the incidence of DMSA abnormalities in children at the time of acute UTI, the progression of these abnormalities following treatment and their correlation with the presence of VUR is reported.</td>
<td>DMSA scans performed within 72 hours of presentation in 65 previously healthy children with acute UTI were abnormal in 34 (52%). The scan appearances of 30/36 (83%) initially abnormal kidneys improved or became normal on the repeat DMSA study performed at 3 to 6 months after the acute UTI. A cystogram demonstrated significant VUR in 11/45 cases (24%). Of these 11 cases 10 had abnormal DMSA studies and 1 had dilated upper tracts on US. The incidence of DMSA abnormalities at the time of acute UTI is high but these abnormalities tend to resolve with time. An abnormal DMSA study at the time of UTI identifies most children with significant VUR, and in the series a combination of US and DMSA identified all cases. This study may have major implications for the clinical investigation of children with UTI.</td>

<td>27. Williams G, Craig J C. Long-term antibiotics for preventing recurrent urinary tract infection in children. <em>Cochrane Database Syst Rev.</em> 2011(3):CD001534.</td>
<td>Meta-analysis</td>
<td>12 studies 1,557 children</td>
<td>To determine the efficacy and harms of long-term antibiotics to prevent recurrent UTI in children.</td>
<td>6 (5 analyzed, 1,069 children) of 12 studies compared antibiotics with placebo/no treatment. Compared to placebo/no treatment, when all studies were included, antibiotics did not appear to reduce the risk of symptomatic UTI (RR 0.75, 95% CI, 0.36 to 1.53) however, when authors evaluated the effects of antibiotics in studies with low risk of bias, there was a statistically significant reduction (RR 0.68, 95% CI, 0.48 to 0.95). The effect was similar in children with VUR (RR 0.65, 95% CI, 0.39 to 1.07) compared to those without VUR (RR 0.56, 95% CI, 0.15 to 2.12). There was no consistency in occurrence of adverse events. 3 studies reported antibiotic resistance, showing a nonsignificant increased risk for resistance to the antibiotic in the active treatment groups (RR 2.4, 95% CI, 0.62 to 9.26). 5 studies (4 analyzed, 367 children) compared 1 antibiotic with another but all compared different combinations or different outcomes and studies were not pooled. 2 studies reported microbial resistance, nitrofurantoin having a significantly lower risk of resistance than cotrimoxazole (RR 0.54, 95% CI, 0.31 to 0.92). 1 study compared alternate with every day cefadroxil treatment. Long-term antibiotics appear to reduce the risk of repeat symptomatic UTI in susceptible children but the benefit is small and must be considered together with the increased risk of microbial resistance.</td>

<td>28. Craig JC, Simpson JM, Williams GJ, et al. Antibiotic prophylaxis and recurrent urinary tract infection in children. <em>N Engl J Med.</em> 2009;361(18):1748-1759.</td>
<td>Review/Other-Dx</td>
<td>11 trials 2,046 children</td>
<td>Systematic review was performed to determine whether long-term antibiotics prevent UTI in children with and without VUR.</td>
<td>Recurrent single symptomatic UTI was not reduced by prophylaxis (RR 0.83, 95% CI, 0.66 to 1.05). Prophylactic efficacy was not affected by a priori subgroup analysis considering children with or without VUR, site of UTI or duration of treatment. It was, however, affected when trials were divided by study quality: in trials with adequate allocation concealment, recurrent UTI was reduced by prophylaxis (RR 0.68, 95% CI, 0.48 to 0.95). Antibiotic prophylaxis reduced the risk of a repeat positive urine culture. There was no significant difference in the rate of new or deteriorated renal scars. The most common adverse events were vomiting or gastrointestinal intolerance (7.3% reported in 1 study). In children with or without VUR, antibiotic prophylaxis may not prevent recurrent symptomatic UTI.</td>

<td>29. Hoberman A, Greenfield SP, Mattoo TK, et al. Antimicrobial prophylaxis for children with vesicoureteral reflux. <em>N Engl J Med.</em> 2014;370(25):2367-2376.</td>
<td>Experimental-Tx</td>
<td>607 children</td>
<td>To determine whether long-term antimicrobial prophylaxis is effective in preventing febrile or symptomatic recurrences and reducing the likelihood of renal scarring, and the extent to which it contributes to bacterial resistance.</td>
<td>Recurrent UTI developed in 39/302 children who received prophylaxis as compared with 72/305 children who received placebo (RR, 0.55; 95% CI, 0.38 to 0.78). Prophylaxis reduced the risk of recurrences by 50% (hazard ratio, 0.50; 95% CI, 0.34 to 0.74) and was particularly effective in children whose index infection was febrile (hazard ratio, 0.41; 95% CI, 0.26 to 0.64) and in those with baseline bladder and bowel dysfunction (hazard ratio, 0.21; 95% CI, 0.08 to 0.58). The occurrence of renal scarring did not differ significantly between the prophylaxis and placebo groups (11.9% and 10.2%, respectively). Among 87 children with a first recurrence caused by Escherichia coli, the proportion of isolates that were resistant to trimethoprim-sulfamethoxazole was 63% in the prophylaxis group and 19% in the placebo group.</td>

<td>Review/Other-Dx</td>
<td>432 articles</td>
<td>Comprehensive review and analysis of literature for diagnosis and management of febrile UTI in children under 2 years of age. Recommendations for the management of UTI are presented.</td>
<td>Gold standard definition of a UTI is growth on a culture of a urine specimen obtained from a tap. PPV of a positive culture from a bagged urine specimen is 15%. Sensitivity and specificity of positive catheterization urine culture is 95% and 99% respectively. Prevalence of VUR drops from ~0.5 to ~0.3 from age 0 to ~2, plateaus at ~0.3 from age ~2 to ~7, and then drops precipitously at age ~7 (based on meta-analysis of 54 studies of VUR in children with UTI). Higher grade of VUR correlates with higher risk of renal scarring (based on meta-analysis of 48 studies). Renal US has low sensitivity for low-grade VUR, but relatively higher sensitivity for high-grade VUR. Renal US alone is an inadequate imaging evaluation for children under age 2 with a febrile UTI. VCUG must also be performed.</td>

<tr>
<td>35.</td>
<td>Review/Other-Dx</td>
<td>131 articles 17,972 patients</td>
<td>To summarize the existing evidence pertaining to children with diagnosed reflux including those young or older than 1 year without evidence of bladder and bowel dysfunction and those older than 1 year with evidence of bladder and bowel dysfunction.</td>
<td>Meta-analysis identified increasing frequency of UTI, increasing grade of VUR and presence of bladder and bowel dysfunction as unique risk factors for renal cortical scarring. The efficacy of continuous antibiotic prophylaxis could not be established with current data. However, its purported lack of efficacy, as reported in selected prospective clinical trials, also is unproven owing to significant limitations in these studies. Reflux resolution and endoscopic surgical success rates are dependent upon bladder and bowel dysfunction. The lack of robust prospective randomized controlled trials limits the strength of these guidelines but they can serve to provide a framework for practice and set boundaries for safe and effective practice. As new data emerge, these guidelines will necessarily evolve.</td>

<td>36. Yang SS, Chiang IN, Lin CD, Chang SJ. Advances in non-surgical treatments for urinary tract infections in children. <em>World J Urol</em>. 2012;30(1):69-75.</td>
<td>Review/Other-Dx</td>
<td>N/A</td>
<td>To review nonsurgical management of UTI in children.</td>
<td>The proposed nonsurgical management of pediatric UTI included behavioral modification (timed voiding and adequate fluids intake), topical steroid for phimosis, nutrient supplements (breast milk, cranberry, probiotics, and vitamin A), biofeedback training for dysfunctional voiding, anticholinergics for reducing intravesical pressure, alpha-blockers in dysfunctional voiding and neurogenic bladder, and intermittent catheterization for children with large postvoid residual urine volume. The published reports usually included small number of patients and were lacking of randomization and controlled group. Further well-designed studies are warranted to support the concepts of nonoperative management for pediatric UTI.</td>

<td>Review/Other-Dx</td>
<td>45 male neonates &lt;8 weeks old</td>
<td>To assess the frequency of urinary tract anomalies in male neonates &lt;8 weeks old who presented with UTI, and to evaluate a suitable imaging approach after the initial infection.</td>
<td>Urinary tract abnormalities were observed in 22/45 male neonates. 19 had VUR, 1 had VUR and a double collecting system, 1 had VUR and a posterior urethral valve, and 1 had an ureteropelvic junction stricture. Renal atrophy or scars, as demonstrated by DMSA scan, were detected almost exclusively in neonates with VUR grade 3 and above. Only 1 neonate with VUR grade 1 had a pathologic DMSA, and the US of this male also demonstrated renal atrophy. Escherichia coli was the pathogen in 62% (28/45), and 9 boys had bacteremia. Authors suggest that US and VCUG should be performed routinely after the initial UTI in male neonates. Renal scan should be reserved for those cases in which the US suggests renal parenchymal damage or when VCUG detects VUR grade 3 and above.</td>

<td>Review/Other-Dx</td>
<td>203 children</td>
<td>Randomized controlled multicenter study to examine the prevalence and types of lower urinary tract dysfunction in children with VUR grades III and IV, and related improved dilating reflux, renal damage and recurrent UTI to dysfunction.</td>
<td>At study entry 20% of patients had lower urinary tract dysfunction, characterized by high bladder capacity and increased post-void residual urine. At 2 years there was dysfunction in 34% of patients. Subdivision into groups characteristic of children after toilet training revealed that 9% had isolated overactive bladder and 24% had voiding phase dysfunction. There was a negative correlation between dysfunction at 2 years and improved dilating reflux (P=0.002). Renal damage at study entry and follow-up was associated with lower urinary tract dysfunction at 2 years (P=0.001). Recurrent UTI were seen in 33% of children with and in 20% without dysfunction (P=0.084). After toilet training a third of these children with dilating reflux had lower urinary tract dysfunction, mainly voiding phase problems. Dysfunction was associated with persistent reflux and renal damage while dysfunction at study entry did not predict the 2-year outcome.</td>

<td>66. Lee HY, Soh BH, Hong CH, Kim MJ, Han SW. The efficacy of ultrasound and dimercaptosuccinic acid scan in predicting vesicoureteral reflux in children below the age of 2 years with their first febrile urinary tract infection. <em>Pediatr Nephrol</em>. 2009;24(10):2009-2013.</td>
<td>Observational-Dx</td>
<td>220 children with first febrile UTI</td>
<td>Retrospective study to evaluate the efficacy of DMSA scan and US in comparison with VCUG in predicting VUR in children below the age of 2 years.</td>
<td>Among 220 children with their first febrile UTI, VUR was detected in 67 (30.4%). The detection rate of VUR by US was 41.7% and 86% in the low (I, II) and high grade (III~IV) groups, respectively. Detection rate of VUR by DMSA scan was 37.5% and 88.4% in the low and high grade groups, respectively. Combining US and DMSA scan, authors found that the detection rate of high grade VUR was 95.3% and that of low grade was 62.5%. During follow up, most of the low grade VURs with normal DMSA and US scans resolved or were downgraded. Most high grade VURs could be detected by US and DMSA scan, but the prediction rate was not as high in low grade VURs.</td>

<td>145 children</td>
<td>Retrospective study to compare radiation exposure and effective dose in children who underwent VCUG performed with grid-controlled variable-rate pulsed fluoroscopy with radiation exposure and effective dose in children who underwent VCUG performed with continuous fluoroscopy and to compare these effective doses with those estimated with radionuclide cystography.</td>
<td>Grid-controlled variable-rate pulsed fluoroscopy resulted in a significant reduction in total radiation exposure, which was at least 8 times lower than that with continuous fluoroscopy in all 3 groups (P&lt;.001 for all). There was no significant difference in fluoroscopy time (P&gt;.50). Effective radiation doses from grid-controlled variable-rate pulsed fluoroscopy were approximately 1 order of magnitude lower than those from continuous fluoroscopy but 1 order of magnitude higher than those from radionuclide cystography. In children, VCUG can be performed with a grid-controlled variable-rate pulsed fluoroscopy unit that delivers radiation exposures that are at least 8 times lower than those delivered by a conventional continuous fluoroscopy unit.</td>

<td>Observational-Dx</td>
<td>124 patients</td>
<td>To compare isotope cystography with cyclic fluoroscopic cystourethrography in children with suspected VUR.</td>
<td>84% concordance between 2 methods in detection of VUR. 93% concordance between 2 methods for detection or exclusion of severe VUR. Fluoroscopic VCUG missed 23/51 (45%) VUR cases including 12 with severe VUR. Isotope cystography missed 3 cases of VUR. Isotope cystography is more accurate than VCUG in diagnosis of VUR, even severe grade.</td>

<td>Observational-Dx</td>
<td>41 patients (82 kidney ureter units)</td>
<td>Direct radionuclide cystography compared to fluoroscopic VCUG for detection of VUR in children with UTI or antenatal hydrenephrosis.</td>
<td>18 refluxing ureters detected by radionuclide cystography, 22 by VCUG, and 14 by both methods. The 2 methods were concordant in 85% of kidney ureter units. VUR missed by VCUG in 4 units and by radionuclide cystography in 8 units. Good correlation between radionuclide cystography and VCUG in evaluation of VUR.</td>

<td>91. Mingin GC, Nguyen HT, Baskin LS, Harlan S. Abnormal dimercapto-succinic acid scans predict an increased risk of breakthrough infection in children with vesicoureteral reflux. <em>J Urol.</em> 2004;172(3):1075-1077; discussion 1077.</td>
<td>Review/Other-Dx</td>
<td>120 consecutive patients</td>
<td>Retrospective review to determine if a delayed DMSA scan in patients with a febrile UTI can help predict which children are at risk for breakthrough UTI.</td>
<td>57/120 abnormal DMSA scans. 88% of these had grade 3-5 VUR, of which 60% had a breakthrough UTI. 63/120 had a normal DMSA scan. 61% of these had grade 3-5 VUR, of which only 5 children had a breakthrough infection. Children with grade 3-5 VUR and an abnormal DMSA scan are at increased risk of breakthrough UTI. DMSA is a useful study for prognostic purposes.</td>

<td>92. Cheng CH, Tsau YK, Lin TY. Is acute lobar nephronia the midpoint in the spectrum of upper urinary tract infections between acute pyelonephritis and renal abscess? <em>J Pediatr.</em> 2010;156(1):82-86.</td>
<td>Review/Other-Dx</td>
<td>115 patients</td>
<td>To examine acute lobar nephronia in the spectrum of upper UTIs between acute pyelonephritis and renal abscess.</td>
<td>The study included 21 patients with acute pyelonephritis, 85 with acute lobar nephronia (63 simple acute lobar nephronia, 22 complicated acute lobar nephronia), and 9 with renal abscesses. The volume fraction of CT lesions correlated well with duration of fever before and after treatment in patients with acute pyelonephritis or simple acute lobar nephronia, and only the correlation between fever duration after treatment and CT lesions was significant in patients with complicated acute lobar nephronia or renal abscess.</td>

### Evidence Table Key

#### Study Quality Category Definitions

- **Category 1**  The study is well-designed and accounts for common biases.
- **Category 2**  The study is moderately well-designed and accounts for most common biases.
- **Category 3**  There are important study design limitations.
- **Category 4**  The study is not useful as primary evidence. The article may not be a clinical study or the study design is invalid, or conclusions are based on expert consensus. For example:
  - a) the study does not meet the criteria for or is not a hypothesis-based clinical study (e.g., a book chapter or case report or case series description);
  - b) the study may synthesize and draw conclusions about several studies such as a literature review article or book chapter but is not primary evidence;
  - c) the study is an expert opinion or consensus document.
- **M = Meta-analysis**

### Abbreviations Key

- ADC = Apparent diffusion coefficient
- CI = Confidence interval
- CRP = C-reactive protein
- CT = Computed tomography
- DMSA = Dimercaptosuccinic acid
- DWI = Diffusion-weighted imaging
- GFR = Glomerular filtration rate
- MRI = Magnetic resonance imaging
- NPV = Negative predictive value
- OR = Odds ratio
- PPV = Positive predictive value
- RR = Relative risk
- SPECT = Single-photon emission tomography
- US = Ultrasound
- UTI = Urinary tract infection
- VUR = Vesicoureteral reflux
- WBC = White blood cell
