<tr>
<td>Review/Other-Dx</td>
<td>4,539 patients</td>
<td>To characterize the patterns and predictors of early pregnancy bleeding, setting aside bleeding episodes that occur at the time of miscarriage.</td>
<td>Approximately one-fourth of participants (n=1,207) reported bleeding (n=1,656 episodes), but only 8% of women with bleeding, reported heavy bleeding. Of the spotting and light bleeding episodes (n=1,555), 28% were associated with pain. Among heavy episodes (n=100), 54% were associated with pain. Most episodes lasted less than 3 days, and most occurred between gestational weeks 5–8. 12% of women with bleeding and 13% of those without experienced miscarriage. Maternal characteristics associated with bleeding included fibroids and prior miscarriage. Consistent with the hypothesis that bleeding is a marker for placental dysfunction, bleeding is most likely to be seen around the time of the luteal-placental shift.</td>
<td>4</td>
</tr>
<tr>
<td>Review/Other-Dx</td>
<td>N/A</td>
<td>To review some of the pitfalls of the modern management of early pregnancy failure and introduce a series of articles on the subject.</td>
<td>No results stated in abstract.</td>
<td>4</td>
</tr>
<tr>
<td>Review/Other-Dx</td>
<td>53 patients; 75 TVUS examinations</td>
<td>Compare TVUS with b-hCG level in the evaluation of embryo in early pregnancy.</td>
<td>b-hCG level of 1000 mIU/ml - gestational sac was seen sonographically in each patient. b-hCG level of 7200 mIU/ml - yolk sac was seen in every patient. 10/22 patients with b-hCG between 1000 and 7200 mIU/ml had a visible yolk sac. Every patient with b-hCG level &gt;10,800 mIU/ml had a visible embryo with a heartbeat. Results support other studies that TVUS can define pregnancy as early as 32 days and at b-hCG levels as low as 1000 mIU/ml.</td>
<td>4</td>
</tr>
<tr>
<td>Observational-Dx</td>
<td>102 patients; 4 observers</td>
<td>Retrospective study to determine if the intradecidual sign at sonography is effective in the diagnosis of early IUP.</td>
<td>Sensitivity for diagnosis of an IUP was 34%-66%, specificity was 55%-73%, accuracy was 38%-65%, PPV was 91%-93%, and NPV was 12%-16%.</td>
<td>2</td>
</tr>
<tr>
<td>Observational-Dx</td>
<td>36 patients with IUP; 5 patients with ectopic</td>
<td>To determine the accuracy of the intradecidual sign (a feature on sonograms) in the detection of early IUP.</td>
<td>Intradecidual sign was more sensitive (91.7% vs 63.9%) and specific (100% vs 60%) than the double decidual sac sign in the detection of early IUP.</td>
<td>4</td>

</tr>
<tr>
<td>7. Doubilet PM, Benson CB. Double sac sign and intradecidual sign in early pregnancy: interobserver reliability and frequency of occurrence. J Ultrasound Med. 2013;32(7):1207-1214.</td>
<td>Observational-Dx</td>
<td>199 sonographic studies</td>
<td>To assess the interobserver agreement, frequency of occurrence, and prognostic importance of the double sac sign (DSS), intradecidual sign (IDS), and other sonographic findings in early intrauterine pregnancies.</td>
<td>Interobserver agreement was poor for the DSS (kappa= 0.24) and IDS (kappa= 0.23). Scans frequently demonstrated neither sign: 150 cases (75.4%) if we considered a sign to be present when both investigators graded it as present and 69 cases (34.7%) using the looser criterion that either graded it as present. The presence of a DSS or an IDS was unrelated to the beta-human chorionic gonadotropin (beta-hCG) value (P &gt; .05, t test, all comparisons). An inner echogenic ring was present in 158 cases (79.4%), and the decidua was brighter peripherally than centrally in 102 (51.3%). The first-trimester outcome was unrelated to the presence of a DSS or an IDS, presence of an inner echogenic ring, or decidual appearance (P &gt; .05, chi(2), all comparisons).</td>

<tr>
<td>8. Richardson A, Gallos I, Dobson S, Campbell BK, Coomarasamy A, Raine-Fenning N. Accuracy of first-trimester ultrasound in diagnosis of intrauterine pregnancy prior to visualization of the yolk sac: a systematic review and meta-analysis. Ultrasound Obstet Gynecol. 2015;46(2):142-149.</td>
<td>Meta-analysis</td>
<td>17 studies</td>
<td>To evaluate the diagnostic accuracy of ultrasound in predicting the location of an intrauterine pregnancy before visualization of the yolk sac is possible.</td>
<td>Seventeen studies including 2564 women were selected from 19 959 potential papers. Following meta-analysis, the presence of a gestational sac on ultrasound examination was found to predict an intrauterine pregnancy with a sensitivity of 52.8% (95% CI, 38.2-66.9%) and specificity of 97.6% (95% CI, 94.3-99.0%). The corresponding performance of the double decidual sac sign, intradecidual sign, chorionic rim sign and yolk sac were: 81.8% (95% CI, 68.1-90.4%) and 97.3% (95% CI, 76.1-99.8%); 66.1% (95% CI, 58.9-72.8%) and 100% (95% CI, 91.0-100%); 79.9% (95% CI, 73.0-85.7%) and 97.1% (95% CI, 89.9-99.6%); and 42.2% (95% CI, 27.7-57.9%) and 100% (95% CI, 54.1-100%), respectively.</td>

<td>9. Richard A, Hopkisson J, Campbell B, Raine-Fenning N. Use of double decidual sac sign to confirm intrauterine pregnancy location prior to sonographic visualization of embryonic contents. Ultrasound Obstet Gynecol. 2017;49(5):643-648.</td>
<td>Observational-Dx</td>
<td>67 women</td>
<td>To determine the diagnostic accuracy of the double decidual sac sign (DDSS) for predicting an intrauterine pregnancy (IUP) prior to visualization of embryonic contents, using modern high-resolution transvaginal sonography (TVS).</td>
<td>A total of 67 intrauterine fluid collections were observed and included in the analysis, of which 61 exhibited the DDSS and 65 were proven to be IUPs. Two ectopic pregnancies were included, neither of which demonstrated the DDSS. The DDSS therefore had a sensitivity of 93.9% (95% CI, 85.0-98.3%), specificity of 100% (95% CI, 15.8-100%) and overall diagnostic accuracy of 94.0% (95% CI, 88.3-99.7%) for predicting an IUP. The negative likelihood ratio and positive and negative predictive values were 0.06 (95% CI, 0.02-0.16), 100% (95% CI, 94.1-100%) and 33.3% (95% CI, 4.3-77.7%), respectively.</td>

</tr>
<tr>
<td>10. Benson CB, Doubilet PM, Peters HE, Frates MC. Intrauterine fluid with ectopic pregnancy: a reappraisal. J Ultrasound Med. 2013;32(3):389-393.</td>
<td>Review/Other-Dx</td>
<td>229 women</td>
<td>To determine the incidence of intrauterine fluid in patients with ectopic pregnancy and to define the characteristics that distinguish this fluid from an early intrauterine gestational sac.</td>
<td>Our study population included 229 women with ectopic pregnancy. In 38 (16.6%), sonography showed fluid in the uterus, which was classified as type A in 31 and type B in 7. Only 2 patients (0.9%) had type B fluid with no adnexal findings suggestive of ectopic pregnancy. Based on these results and the published incidence of ectopic pregnancy (2% of all pregnancies), we calculated that a patient with a positive pregnancy test, an intrauterine smooth-walled anechoic cystic structure, and no adnexal mass has a 0.02% probability of ectopic pregnancy, while the probability of intrauterine pregnancy in such a patient is 99.98%.</td>

<tr>
<td>11. Ackerman TE, Levi CS, Lyons EA, Dashfsky SM, Lindsay DJ, Holt SC. Decidual cyst: endovaginal sonographic sign of ectopic pregnancy. Radiology. 1993;189(3):727-731.</td>
<td>Observational-Dx</td>
<td>467 cases</td>
<td>To determine the prevalence of decidual cysts in patients with ectopic pregnancy and assess the value of endovaginal sonographic demonstration of decidual cysts in predicting ectopic pregnancy.</td>
<td>Decidual cysts were identified in 30 (14.4%) of 208 ectopic pregnancies. In 12 patients a decidual cyst was the first sonographic sign of ectopic pregnancy, and in six patients it was the only abnormal sonographic finding. Four of five patients with decidual cysts had an ectopic pregnancy. Decidual cysts had a sensitivity of 21%, specificity of 92%, positive predictive value of 80%, and negative predictive value of 42% in the diagnosis of ectopic pregnancy.</td>

<td>12. Mehta TS, Levine D, Beckwith B. Treatment of ectopic pregnancy: is a human chorionic gonadotropin level of 2,000 mIU/mL a reasonable threshold? Radiology. 1997;205(2):569-573.</td>
<td>Review/Other-Dx</td>
<td>676 patients</td>
<td>Review medical records and US scans to determine whether hCG level of 2,000 mIU/ml is a reasonable threshold for diagnosing ectopic pregnancy in the absence of US findings of IUP in order to prevent inappropriate treatment.</td>
<td>548 patients had evidence of a normal or abnormal IUP. 51 (40%) of the 128 patients without evidence of an IUP had an hCG level &gt;2,000 mIU/mL. Of 51 patients, 15 (29%) were treated for ectopic pregnancy; 17 (33%) were not immediately treated for ectopic pregnancy and had a normal IUP at follow-up US. hCG level of 2,000 mIU/ml without US findings of IUP is not diagnostic.</td>
<td>4</td>
</tr>
<tr>
<td>13. Nyberg DA, Filly RA, Mahony BS, Monroe S, Laing FC, Jeffrey RB, Jr. Early gestation: correlation of HCG levels and sonographic identification. AJR. 1985;144(5):951-954.</td>
<td>Review/Other-Dx</td>
<td>49 patients</td>
<td>Compare hCG levels with US findings in patients with normal early IUP to determine the discriminatory level of ß-hCG.</td>
<td>A gestational sac was always visible when the hCG level was &gt;1800 mIU/ml in 36 cases and &gt;357 mIU/ml in one case. Comparison of serum hCG levels with US detection is useful for evaluating early pregnancy.</td>
<td>4</td>
</tr>
<tr>
<td>14. Connolly A, Ryan DH, Stuebe AM, Wolfe HM. Reevaluation of discriminatory and threshold levels for serum beta-hCG in early pregnancy. Obstet Gynecol. 2013;121(1):65-70.</td>
<td>Review/Other-Dx</td>
<td>651 pregnancies</td>
<td>To reevaluate both discriminatory and threshold levels associated with visualization of gestational sacs, yolk sacs, and fetal poles in patients presenting with vaginal bleeding, pain, or vaginal bleeding and pain in the first trimester of pregnancy using current US technology.</td>
<td>651 pregnancies met inclusion criteria; 366 were viable. Discriminatory beta-hCG levels at which structures would be predicted to be seen 99% of the time were 3,510 mIU/mL, 17,716 mIU/mL, and 47,685 mIU/mL for gestational sac, yolk sac, and fetal pole, respectively. In this population, threshold values for beta-hCG levels at which these structures could be seen were 390 mIU/mL, 1,094 mIU/mL, and 1,394 mIU/mL, respectively.</td>
<td>4</td>
</tr>
<tr>
<td>15. Doubilet PM, Benson CB. Further evidence against the reliability of the human chorionic gonadotropin discriminatory level. J Ultrasound Med. 2011; 30(12):1637-1642.</td>
<td>Observational-Dx</td>
<td>202 patients</td>
<td>To determine whether a woman with a ß-hCG above 2000 mIU/mL and no intrauterine fluid collection on TVUS can subsequently be found to have a live intrauterine gestation and, if so, what the prognosis is for the pregnancy.</td>
<td>162 (80.2%) women had ß-hCG levels below 1000 mIU/mL on the day of the initial scan showing no intrauterine fluid collection, 19 (9.4%) with levels of 1000 to 1499, 12 (5.9%) 1500 to 1999, and 9 (4.5%) above 2000 mIU/mL. There was no significant relationship between initial ß-hCG level and either first-trimester outcome or final pregnancy outcome (P&gt;0.05, logistic regression analysis and Fisher exact test). The highest ß-hCG was 6567 mIU/mL, and the highest value that preceded a liveborn term baby was 4336 mIU/mL. The hCG discriminatory level should not be used to determine the management of a hemodynamically stable patient with suspected ectopic pregnancy, if sonography demonstrates no findings of intrauterine or ectopic pregnancy.</td>

<tr>
<td>19. Abdallah Y, Daemen A, Kirk E, et al. Limitations of current definitions of miscarriage using mean gestational sac diameter and crown-rump length measurements: a multicenter observational study. Ultrasound Obstet Gynecol. 2011;38(5):497-502.</td>
<td>Observational-Dx</td>
<td>1,060 consecutive women</td>
<td>Observational cross-sectional study to define the false-positive rate for the diagnosis of miscarriage associated with different CRL and MSD measurements with or without a yolk sac in a large study population of patients attending early pregnancy clinics. The authors also aimed to define cut-off values for CRL and MSD that, on the basis of a single measurement, can definitively diagnose a miscarriage and so exclude possible inadvertent termination of pregnancy.</td>
<td>Of the 1,060 women with a diagnosis of IUP of uncertain viability, 473 remained viable and 587 were non-viable by the time of the 11-14-week scan. In the absence of both embryo and yolk sac, the false-positive rate for miscarriage was 4.4% when an MSD cut-off of 16 mm was used and 0.5% for a cut-off of 20 mm. There were no false-positive test results for miscarriage when a cut-off of MSD =21 mm was used. If a yolk sac was present but an embryo was not, the false-positive rate for miscarriage was 2.6% for an MSD cut-off of 16 mm and 0.4% for a cut-off of 20 mm, with no false-positive results when a cut-off of MSD =21 mm was used. When an embryo was visible with an absent heartbeat, using a CRL cut-off of 4 mm the false-positive rate for miscarriage was 8.3%, and for a CRL cut-off of 5 mm it was also 8.3%. There were no false-positive results using a CRL cut-off of =5.3 mm. These data show that some current definitions used to diagnose miscarriage are potentially unsafe. An MSD cut-off of &gt;25 mm and a CRL cut-off of &gt;7 mm could be introduced to minimize the risk of a false-positive diagnosis of miscarriage.</td>

<tr>
<td>28. Yegul NT, Filly RA. The expanded amnion sign: evidence of early embryonic death. J Ultrasound Med. 2009;28(10):1331-1335.</td>
<td>Observational-Dx</td>
<td>806 patients</td>
<td>Retrospective study was performed to assess the PPV for confirming early embryonic death in the clinical scenario wherein an embryo is identified without a visible heartbeat, but the embryonic CRL is ≈5 mm.</td>
<td>Among the cohort of 806 cases, 520 (64.5%) had an identifiable embryo, and 255 of those with an identifiable embryo had a visible amnion (49.0%). 116/255 with a visible amnion and an identifiable embryo without a heartbeat had a CRL that measured ≈5 mm (45.5%). The CRL of these embryos ranged from 1.7 to 5.4 mm (ie, when rounded to the nearest millimeter, these embryos would be 5 mm) with the breakdown as follows: those measuring ≈3.4 mm (n=28), those measuring 3.5 to 4.4 mm (n=45), and those measuring 4.5 to 5.4 mm (n=43). Eight of these 116 patients did not have any documented follow-up. In the remaining 108 patients, pregnancy failure was confirmed. Authors conclude that any embryo that is surrounded by an amnion and that also lacks a heartbeat has unfortunately but definitively died. This is equally true for embryos measuring &lt;5 mm in CRL.</td>

<td>Review/Other-Dx</td>
<td>114 cases</td>
<td>To review the corpus luteum and tubal pregnancy.</td>
<td>A corpus luteum was found ipsilateral to the tubal pregnancy in 80 cases (70%) and contralateral in 18 (16%). In 16 cases (14%), the position of the corpus luteum could not be identified by inspection. No differences were noted among the groups in days from last normal menstrual period or the incidence of irregular bleeding. Of the 98 cases in which a corpus luteum was identified, 53 women (54%) had at least one condition that could be considered etiologic for tubal pregnancy, including 38 (39%) who had microscopic evidence of chronic salpingitis. No association was found between the laterality of the corpus luteum and the presence of risk factors, including mechanical factors.</td>

<td>Review/Other-Dx</td>
<td>160 patients</td>
<td>To describe the gray-scale and Doppler sonographic features of the corpus luteum during the first trimester of pregnancy.</td>
<td>The corpus luteum was identified in 157 (98%) of 160 patients. The mean diameter was 1.9 +/- 0.6 cm. The most common appearance was a round hypoechoic structure, found in 54 patients (34%). Other appearances included a cyst with a thick wall and anechoic center (43 patients, 27%), a cyst containing internal debris (36 patients, 23%), and a thin-walled simple cyst (24 patients, 15%). Corpus luteal blood flow was visualized with color Doppler imaging in 92% (145/157) of patients in whom the corpus luteum was found. Color Doppler imaging typically revealed a circumferential rim surrounding part or all of the corpus luteum. Low-resistance blood flow was seen with pulsed Doppler interrogation, with a mean resistance index of 0.49 +/- 0.08 and mean peak systolic velocity of 17 +/- 10 cm/second.</td>

<td>38. Frates MC, Doubilet PM, Durfee SM, et al. Sonographic and Doppler characteristics of the corpus luteum: can they predict pregnancy outcome? J Ultrasound Med. 2001;20(8):821-827.</td>
<td>Observational-Dx</td>
<td>201 patients</td>
<td>To determine whether there is a relationship between gray scale or Doppler characteristics of the corpus luteum and first-trimester pregnancy outcome.</td>
<td>There were 201 study patients. The corpus luteum could be visualized in 197 (98%) and had a mean +/- SD size of 1.9 +/- 0.6 cm, a mean resistive index of 0.50 +/- 0.08, and a peak systolic velocity of 20.5 +/- 11.2 cm/s. There were 151 first-trimester survivors (75.1%) and 50 spontaneous losses (24.9%). In a comparison of the survivors and losses, there was no significant difference in mean corpus luteum size (1.9 versus 1.7 cm; P = .10, t test), mean resistive index (0.50 versus 0.50; P = .71, t test), peak systolic velocity (21 versus 19 cm/s; P = .29, t test), or sonographic appearance (P = .78, chi2 test). The lack of association between corpus luteum characteristics and outcome persisted when cases were stratified by progesterone use and the presence or absence of a heartbeat on the study sonogram.</td>

<td>39. Frates MC, Doubilet PM, Peters HE, Benson CB. Adnexal sonographic findings in ectopic pregnancy and their correlation with tubal rupture and human chorionic gonadotropin levels. J Ultrasound Med. 2014;33(4):697-703.</td>
<td>Observational-Dx</td>
<td>231 pregnancies</td>
<td>To determine whether the distribution of transvaginal sonographic findings of ectopic pregnancy has changed since the studies done 20 years ago and to explore the correlation of tubal rupture with transvaginal sonographic findings and human chorionic gonadotropin (hCG) levels.</td>
<td>Our study included 231 ectopic pregnancies. A positive sonographic adnexal finding was present in 219 cases (94.8%): adnexal mass in 218 (94.4%) and a moderate-to-large amount of free fluid in 84 (36.4%). The adnexal masses were graded as follows: 1, nonspecific mass (125 cases [54.1% of total]); 2, tubal ring without a yolk sac or embryo (57 [24.7%]); 3, yolk sac but no embryonic heartbeat (19 [8.3%]); and 4, embryo with cardiac activity (17 [7.4%]). The mean hCG level increased as the grade ascended from 1 to 4. Thirty-six patients had tubal rupture at surgery within 24 hours of the sonogram. A moderate-to-large amount of free fluid was significantly associated with tubal rupture (P &lt; .05) but had low sensitivity, specificity, and positive predictive value for rupture. Other sonographic findings and hCG levels were not significantly related to tubal rupture.</td>

<td>40. Rottem S, Thaler I, Timor-Tritsch IE. Classification of tubal gestations by transvaginal sonography. Ultrasound Obstet Gynecol. 1991;1(3):197-201.</td>
<td>Observational-Dx</td>
<td>191 patients</td>
<td>To identify the classification of tubal gestations by transvaginal sonography</td>
<td>The following classifications were made: Type Ia (n = 43) A well-defined 'tubal ring' and a beating heart with or without discrete embryonic or extra-embryonic structures. Type Ib (n = 48) A 'tubal ring' containing embryonic and/or extra-embryonic structures without heart beats. Type II (n = 64) An ill-defined or thin tubal wall containing sonolucent or an irregularly echogenic core but not embryonic or extra-embryonic structures. Type III (n = 28) Free pelvic fluid and an empty uterus in patients with positive serum beta-hCG levels. The outline of the tube cannot be visualized. Surgery revealed unruptured tubal pregnancies in 90 patients of the combined groups of Types Ia and Ib. In one additional patient, a tubal rupture was found. In the Type II patients, 26 tubal pregnancies with blood clots in the tube but no evidence of bleeding into the pelvis, and 38 tubal ruptures or abortions were diagnosed. All Type III patients had ruptured tubal pregnancies or bleeding tubal abortions. In eight patients (4.2%), the only sonographic finding was an empty uterus, and these cases were erroneously diagnosed as not having an ectopic pregnancy (false negatives). There were two false-positive cases in which a tubal ring was detected, and this was related to an hemorrhagic corpus luteum. When used for diagnosing tubal pregnancy, the transvaginal scanning technique (together with beta-hCG in Type III cases) carries a sensitivity of 95.8% and specificity of 99.9%.</td>

<td>56. Frates MC, Brown DL, Doubilet PM, Hornstein MD. Tubal rupture in patients with ectopic pregnancy: diagnosis with transvaginal US. Radiology. 1994;191(3):769-772.</td>
<td>Observational-Dx</td>
<td>132 consecutive patients</td>
<td>Retrospective review of US scans and medical records to determine whether sonography can help diagnose tubal rupture in patients with ectopic pregnancy.</td>
<td>Adnexal masses were seen in 93 patients at US. Thirty-four patients had a tubal ring, and 59 had a complex mass. The frequency of tubal rupture was similar for both groups. The adnexal mass was significantly smaller in patients without a ruptured tube, but there was considerable overlap. Rupture was present in 21% of patients with no sign of or a trace of intraperitoneal fluid, increasing steadily to 63% in patients with a large amount of free fluid. Even though the amount of fluid was the best predictor of rupture, it was not completely reliable, as 37% of patients in whom a large amount of fluid was found had intact tubes. Findings at TVUS cannot reliably determine whether tubal rupture is present.</td>

<td>106/355 cases had hydatidiform mole, 33 had a partial hydatidiform mole, 184 had an invasive hydatidiform mole, and 32 had choriocarcinoma. US showed abnormal molar tissue confined to the endometrial cavity in all cases of hydatidiform mole. Doppler waveforms showed resistive indices of 0.55 for hydatidiform mole, 0.56 for partial hydatidiform mole, 0.28 for invasive hydatidiform mole, 0.25 for choriocarcinoma, and 0.66 for normal pregnancies. Sonography and Doppler imaging were helpful in diagnosing GTD, in determining whether invasive disease was present, in detecting recurrence of disease, and in following the effectiveness of chemotherapy.</td>

<td>62. Timor-Tritsch IE, Haynes MC, Monteagudo A, Khatib N, Kovacs S. Ultrasound diagnosis and management of acquired uterine enhanced myometrial vascularity/arteriovenous malformations. Am J Obstet Gynecol. 2016;214(6):731 e731-731 e710.</td>
<td>Observational-Tx</td>
<td>27 patients</td>
<td>To evaluate the role of transvaginal ultrasound scanning in the diagnosis and treatment of acquired enhanced myometrial vascularity/arteriovenous malformations to outline the natural history of conservatively followed vs treated lesions.</td>
<td>Twenty-seven patients met the diagnostic criteria of uterine enhanced myometrial vascularity/arteriovenous malformation. Mean age was 31.8 years (range, 18-42 years). Clinical diagnoses of the patients included 10 incomplete abortions, 6 missed abortions, 5 spontaneous complete abortions, 5 cesarean scar pregnancies, and 1 molar pregnancy. Eighty-nine percent of patients had bleeding (n = 24/27), although 1 patient was febrile, and 2 patients were asymptomatic. Recent surgical procedures were performed in 55.5% patients (15/27) that included curettage (n = 10), cesarean deliveries (n = 5), or both (n = 1); 4 patients had a remote history of uterine surgery that included myomectomy. Treatment was varied and included expectant treatment alone in 48% of the patients with serial ultrasound scans and serum human chorionic gonadotropin until resolution (n = 13/27 patients), uterine artery embolization (29.6%; 8/27 patients), methotrexate administration (22.2%; 6/27 patients), hysterectomy (7.4%; 2/27 patients), and curettage (3.7%; 1/27 patients). Three patients required a blood transfusion. Of the 9 patients whose condition required embolization, the conditions of 7 patients resolved after the procedure although 1 patient's condition required operative hysteroscopy and 1 patient's condition required hysterectomy for intractable bleeding. Average peak systolic velocity after embolization in the 9 patients was 85.2 cm/sec (range, 35-170 cm/sec); the average peak systolic velocity of the 16 patients with spontaneous resolution was 58.5 cm/sec (range, 23-90 cm/sec).</td>

<td>Rufener SL, Adusumilli S, Weadock WJ, Caoili E. Sonography of uterine abnormalities in postpartum and postabortion patients: a potential pitfall of interpretation. J Ultrasound Med. 2008;27(3):343-348.</td>
<td>Observational-Dx</td>
<td>29 patients</td>
<td>To identify misleading imaging features that leads to inclusion of a uterine AVM in the differential diagnosis of a uterine abnormality because consideration of this diagnosis can potentially alter patient treatment.</td>
<td>Interobserver agreement was as follows: the presence of a uterine mass, 90%; myometrial involvement, 83%; the presence of an associated vascular abnormality, 72%; and inclusion of a uterine AVM in the differential diagnosis, 86%. Myometrial involvement showed a statistically significant relationship to inclusion of a uterine AVM in the differential diagnosis (P&lt;.05). Final pathologic diagnoses included retained products of conception (n=26), an endometrial polyp (n=1), chronic endometritis (n=1), and an exogenous progestational effect (n=1). No uterine AVMs were found. Despite high interobserver agreement in characterizing uterine abnormalities on sonography, readers still include uterine AVMs in the differential diagnosis of uterine masses that are ultimately proven to be retained products of conception. A myometrial location of a uterine mass is a particularly misleading imaging feature of retained products of conception.</td>

### Reference Study Type Patients/Events Study Objective (Purpose of Study) Study Results

**Observational-Dx** 30 patients To assess the spontaneous outcome of uterine vascular malformations detected with ultrasonography and color Doppler, and to investigate the predictive value of color Doppler imaging as to which patients require invasive treatment.

A total of 30 consecutive patients with uterine vascular malformations were included in the study. Spectral analysis of the vessels in the vascular malformations within the myometrium and endometrium revealed the presence of a low-impedance and high-velocity flow. The average values for PI, RI, peak systolic velocity (PSV) and time-averaged maximum velocity (TAMXV) were 0.50, 0.38, 0.63 m/s and 0.46 m/s, respectively. Eight patients (27%) eventually required embolization of the uterine arteries and three of them had true arteriovenous malformations confirmed at angiography. PSV values of \( \geq 0.83 \) m/s were associated with higher probabilities of further treatment, such as an embolization, whereas no vascular malformation with a PSV value \(< 0.39 \) m/s required embolization.

**Review/Other-Dx** N/A To describe the CT and MRI findings of early intrauterine pregnancy.

No results listed in abstract.

**Review/Other-Dx** N/A To discuss various forms of ectopic pregnancy and its complications that may occasionally be further evaluated with MRI or may be incidentally detected on CT or MRI when an alternative diagnosis is suspected.

No results stated in abstract.

**Review/Other-Dx** 2 patients Case report to examine role of MRI in interstitial pregnancy.

MRI was able to localize the ectopic pregnancy by showing a gestational structure surrounded by a thick wall in the upper part of the uterine wall separated from the endometrium by an uninterrupted junctional zone in both cases.

**Review/Other-Dx** 12 patients To assess characteristic MR findings of cervical pregnancy.

Typical MR finding for cervical pregnancy is heterogeneous hemorrhagic mass with densely enhancing papillary solid components.

<td>71. Peng KW, Lei Z, Xiao TH, et al. First trimester caesarean scar ectopic pregnancy evaluation using MRI. Clin Radiol. 2014;69(2):123-129.</td>
<td>Observational-Dx</td>
<td>39 patients</td>
<td>To determine the features of caesarean scar ectopic pregnancy (CSP) by using magnetic resonance imaging (MRI) in the first trimester.</td>
<td>The CSPs were categorized into three groups: type I, in which a thin-walled diverticulum is present at the caesarean section scar (CSS) defect and the gestational sac (GS) is embedded in the diverticulum; type II, in which a thin-walled diverticulum is present at the CSS defect and the GS is partially embedded in the diverticulum; type III, in which a niche is present in the CSS defect and the GS is mainly embedded in the isthmus. Types I, II, and III CSP occurred in 40, 46, and 14% of the women, respectively. There was no significant difference between the three types in the minimum thickness of the CSS defect. In types I and II, there was a positive correlation in the maximum inlet diameter of the CSS defect and the approximate area of the GS.</td>

<td>Observational-Dx</td>
<td>1,424,105 children</td>
<td>To evaluate the long-term safety after exposure to MRI in the first trimester of pregnancy or to gadolinium at any time during pregnancy.</td>
<td>Of 1424105 deliveries (48% girls; mean gestational age, 39 weeks), the overall rate of MRI was 3.97 per 1000 pregnancies. Comparing first-trimester MRI (n = 1737) to no MRI (n = 1418451), there were 19 stillbirths or deaths vs 9844 in the unexposed cohort (adjusted relative risk [RR], 1.68; 95% CI, 0.97 to 2.90) for an adjusted risk difference of 4.7 per 1000 person-years (95% CI, -1.6 to 11.0). The risk was also not significantly higher for congenital anomalies, neoplasm, or vision or hearing loss. Comparing gadolinium MRI (n = 397) with no MRI (n = 1418451), the hazard ratio for NSF-like outcomes was not statistically significant. The broader outcome of any rheumatological, inflammatory, or infiltrative skin condition occurred in 123 vs 384180 births (adjusted HR, 1.36; 95% CI, 1.09 to 1.69) for an adjusted risk difference of 45.3 per 1000 person-years (95% CI, 11.3 to 86.8). Stillbirths and neonatal deaths occurred among 7 MRI-exposed vs 9844 unexposed pregnancies (adjusted RR, 3.70; 95% CI, 1.55 to 8.85) for an adjusted risk difference of 47.5 per 1000 pregnancies (95% CI, 9.7 to 138.2).</td>

Evidence Table Key

Study Quality Category Definitions

- **Category 1**: The study is well-designed and accounts for common biases.
- **Category 2**: The study is moderately well-designed and accounts for most common biases.
- **Category 3**: There are important study design limitations.
- **Category 4**: The study is not useful as primary evidence. The article may not be a clinical study or the study design is invalid, or conclusions are based on expert consensus. For example:
  a) the study does not meet the criteria for or is not a hypothesis-based clinical study (e.g., a book chapter or case report or case series description);
  b) the study may synthesize and draw conclusions about several studies such as a literature review article or book chapter but is not primary evidence;
  c) the study is an expert opinion or consensus document.
- **M** = Meta-analysis

Dx = Diagnostic
Tx = Treatment
