<td>1.  Kulkarni AD, Jamieson DJ, Jones HW, Jr., et al. Fertility treatments and multiple births in the United States. <em>N Engl J Med.</em> 2013;369(23):2218-2225.</td>
<td>Review/Other-Dx</td>
<td>N/A</td>
<td>To conduct a longitudinal analysis to determine the trends in and magnitude of the contribution of fertility treatments to multiple births.</td>
<td>We estimated that by 2011, a total of 36% of twin births and 77% of triplet and higher-order births resulted from conception assisted by fertility treatments. The observed incidence of twin births increased by a factor of 1.9 from 1971 to 2009. The incidence of triplet and higher-order births increased by a factor of 6.7 from 1971 to 1998 and decreased by 29% from 1998 to 2011. This decrease coincided with a 70% reduction in the transfer of 3 or more embryos during in vitro fertilization (<em>P</em>&lt;0.001) and a 33% decrease in the proportion of triplet and higher-order births attributable to in vitro fertilization (<em>P</em>&lt;0.001).</td>

<td>4.  Ghai V, Vidyasagar D. Morbidity and mortality factors in twins. An epidemiologic approach. <em>Clin Perinatol.</em> 1988;15(1):123-140.</td>
<td>Review/Other-Dx</td>
<td>N/A</td>
<td>To review the epidemiologic characteristics of twin pregnancies and twin infants.</td>
<td>We found that twins are prone to be born prematurely and have lower birth weights than their singleton counterparts after 30 to 34 weeks of gestation. Twins are also more prone to birth asphyxia, hyaline membrane disease, respiratory disorders, and seizures. Congenital anomalies and nonrespiratory morbidity were not found to be increased in twins. Twins have a 6 times higher perinatal mortality rate than do singletons. This is accounted for by prematurity in the main. A part of the excess mortality in twins is accounted for by a higher mortality in larger, near-term twins.</td>

<td>5. Morin L, Lim K. Ultrasound in twin pregnancies. <em>J Obstet Gynaecol Can.</em> 2011;33(6):643-656.</td>
<td>Review/Other-Dx</td>
<td></td>
<td>To review the literature with respect to the use of diagnostic US in the management of twin pregnancies. To make recommendations for the best use of US in twin pregnancies.</td>
<td>1. There are insufficient data to make recommendations on repeat anatomical assessments in twin pregnancies. Therefore, a complete anatomical survey at each scan may not be needed following a complete and normal assessment. 2. There are insufficient data to recommend a routine preterm labor surveillance protocol in terms of frequency, timing, and optimal cervical length thresholds. 3. Singleton growth curves currently provide the best predictors of adverse outcome in twins and may be used for evaluating growth abnormalities. 4. It is suggested that growth discordance be defined using either a difference (20 mm) in absolute measurement in abdominal circumference or a difference of 20% in US-derived EFW. 5. Although there is insufficient evidence to recommend a specific schedule for US assessment of twin gestation, most experts recommend serial US assessment every 2 to 3 weeks, starting at 16 weeks of gestation for monochorionic pregnancies and every 3 to 4 weeks, starting from the anatomy scan (18 to 22 weeks) for dichorionic pregnancies. 6. Umbilical artery Doppler may be useful in the surveillance of twin gestations when there are complications involving the placental circulation or fetal hemodynamic physiology. 7. Although many methods of evaluating the level of amniotic fluid in twins have been described, there is not enough evidence to suggest that 1 method is more predictive than the others of adverse pregnancy outcome. 8. Referral to an appropriate high-risk pregnancy center is indicated when complications unique to twins are suspected on US. These complications include: 1. TTTS 2. Monoamniotic twins gestation 3. Conjoined twins 4. Twin reversed arterial perfusion sequence 5. Single fetal death in the second or third trimester 6. Growth discordance in monochorionic twins.</td>

<td>9. Finberg HJ. The “twin peak” sign: reliable evidence of dichorionic twinning. J Ultrasound Med. 1992;11(11):571-577.</td>
<td>Review/Other-Dx</td>
<td>15 twin pregnancies</td>
<td>To describe an observation, dubbed the “twin peak” sign, which, when present, confirms that the twin pregnancy is dichorionic.</td>
<td>This observation, dubbed the “twin peak” sign, was identified in 15 twin pregnancies, all proven to be dichorionic at birth, and in 5 triplet pregnancies, all proven to be trichorionic. This finding is produced by proliferating chorionic villi growing into the potential space between the 2 layers of chorion in the intertwin membrane. The single chorion of a monoplacental twin pregnancy serves as an intact barrier, preventing villi from growing between the 2 amniotic layers.</td>

<td>Review/Other-Dx</td>
<td>32 monoamniotic pregnancies</td>
<td>To assess the prevalence of cord entanglement and perinatal outcome in a large series of monoamniotic twin pregnancies and to review the recent literature on similar published large series.</td>
<td>A total of 32 monoamniotic pregnancies were diagnosed during the study period, including 3 conjoined twins, 7 pregnancies with TRAP syndrome, 3 surgical pregnancy interruptions for discordant fetal abnormality and 1 miscarriage before 16 weeks’ gestation. The remaining 18 monoamniotic pregnancies were included in the study analysis. All monoamniotic pregnancies were complicated with antenatal cord entanglement diagnosed by B-mode and color Doppler US. There were 34 live births and a double intrauterine death diagnosed at 19 + 2 weeks’ gestation. There were 2 late neonatal deaths, 1 from congenital complete heart block and the other after surgery for transposition of the great arteries. The overall perinatal loss rate was 11.1% after 16 weeks and 5.9% after 20 weeks’ gestation. The cumulative rates of cord entanglement and perinatal mortality in the reviewed literature were 74% and 21%, respectively.</td>

<tr>
<td>19. Kagan KO, Gazzoni A, Sepulveda-Gonzalez G, Sotiriadis A, Nicolaides KH. Discordance in nuchal translucency thickness in the prediction of severe twin-to-twin transfusion syndrome. <em>Ultrasound Obstet Gynecol.</em> 2007;29(5):527-532.</td>
<td>Observational-Dx</td>
<td>512 monochorionic twin pregnancies</td>
<td>To examine in monochorionic pregnancies the possible value of intertwin discordance in NT thickness in the prediction of early fetal death or severe TTTS.</td>
<td>In 412 (80.5%) pregnancies there was a normal outcome, in 58 (11.3%) there was severe TTTS requiring endoscopic laser surgery at 18–24 weeks, in 19 (3.7%) there was death of 1 or both fetuses at 13–18 weeks and in 23 (4.5%) there was fetal death at 21–38 weeks. In the 4 outcome groups the median discordance in NT was 11%, 22%, 35% and 7%, respectively. Significant prediction of early fetal death and severe TTTS was provided by the discordance in fetal NT, which was not significantly improved by including the discordance in CRL. If the discordance in NT was 20% or more, the false positive rate was 20%, the detection rate of early fetal death was 63% and the detection rate of severe TTTS was 52%.</td>

<td>24. Fuchs F, Senat MV. Multiple gestations and preterm birth. <em>Semin Fetal Neonatal Med.</em> 2016;21(2):113-120.</td>
<td>Review/Other-Dx</td>
<td>N/A</td>
<td>To review the existing literature regarding the prediction and prevention of preterm birth in both symptomatic and asymptomatic twin pregnancies.</td>
<td>In asymptomatic twin pregnancies, the best 2 predictive tests were cervical length measurement and cervicovaginal fetal fibronectin testing. A single measurement of transvaginal cervical length at 20-24 weeks of gestation &lt;20 mm or &lt;25 mm is a good predictor of spontaneous preterm birth at &lt;28, &lt;32, and &lt;34 weeks of gestation. A cervical length beyond 25 mm is associated with a 2% risk for birth before 28 weeks and with a 65% chance for a term pregnancy. Cervicovaginal fetal fibronectin may be slightly less accurate than cervical length; however, it has a high negative predictive value in women presenting with threatened preterm labor, as &lt;2% of these women will deliver within 1 week if the fetal fibronectin is negative. In symptomatic twin pregnancies, no tests have proven accurate in predicting the risk of preterm birth. For the prevention of preterm birth in asymptomatic twins, regardless of cervical length, no treatment including bed rest, limitation of home activities, prophylactic tocolysis, progesterone, or cerclage has been shown to reduce the rate of preterm birth.</td>

<td>100 pregnancies</td>
<td>To assess myocardial performance index measured by conventional Doppler (MPI) and by tissue Doppler imaging (MPI') at 18 weeks’ gestation in MCDA twins for the prediction of TTTS.</td>
<td>Of the 100 pregnancies, 88 were controls (84 uncomplicated and 4 developed sIUGR) and 12 developed TTTS. Right ventricle-conventional Doppler and left ventricle-conventional Doppler, and left ventricle-tissue Doppler imaging were significantly higher in future TTTS recipients than in controls, while right ventricle-tissue Doppler imaging was significantly lower in donors. Right ventricle-conventional Doppler and left ventricle-conventional Doppler were found to be predictive indicators in pregnancies that had not yet developed TTTS. Their negative predictive values were &gt;90%, and their specificities &gt;80%. The best performing index left ventricle-tissue Doppler imaging, with a sensitivity of 91.7% and specificity of 88.6%.</td>

<tr>
<td>32. Eschbach SJ, Boons LS, van Zwet E, et al. Right ventricular outflow tract obstruction in complicated monochorionic twin pregnancies. <em>Ultrasound Obstet Gynecol.</em> 2016:[Epub ahead of print].</td>
<td>Observational-Dx</td>
<td>485 pregnancies</td>
<td>To evaluate pregnancy characteristics of neonates with RVOTO in complicated monochorionic twin pregnancies.</td>
<td>A total of 485 twin pregnancies received laser therapy for TTTS. RVOTO was diagnosed in 3.0% (11/385) of the live born TTTS-recipients. 2 of them showed a mild Ebstein anomaly additionally. Before laser therapy, pericardial effusion was seen in 45% (5/11) of RVOTO cases ($P&lt;0.01$), abnormal A-wave in ductus venosus was seen in 73% (8/11) ($P=0.03$) and gestational age at time of laser therapy was 17w3d compared to 20w3d in controls ($P=0.03$). A prediction model was constructed. 1 donor had RVOTO after development of transient hydrops after laser therapy. 3 larger twins in pregnancies complicated by sIUGR developed RVOTO, in all 3 cases onset of RVOTO was visible in early second trimester.</td>

<td><strong>33.</strong> Sassoon DA, Castro LC, Davis JL, Hobel CJ. Perinatal outcome in triplet versus twin gestations. <em>Obstet Gynecol.</em> 1990;75(5):817-820.</td>
<td>Observational-Dx</td>
<td>15 triplet and twin pregnancies</td>
<td>To determine whether triplet pregnancies are associated with a significantly worse perinatal outcome than twin pregnancies.</td>
<td>Maternal and neonatal outcome was evaluated in 15 triplet and twin pregnancies that were matched for maternal age, race, type of medical insurance, delivery mode, parity, and history of previous preterm delivery. Preterm labor occurred significantly more often in triplet than in twin gestations (80% vs 40%), as did preterm delivery (87% vs 26.7%). Triplets had a significantly lower mean birth weight (1720 vs 2475 g) and gestational age at delivery (33 vs 36.6 weeks). In addition, 53.3% of triplet pregnancies but only 6.7% of twin pregnancies had 1 or more neonates with intrauterine growth retardation. Discordancy also occurred more frequently in triplets than in twins (66.7 vs 13.3%). The mean averaged neonatal hospital stay was significantly higher in triplets (29 vs 8.5 days), and triplets had a fivefold increased risk of requiring neonatal intensive care as compared with twins. However, there were no significant differences between the groups in maternal morbidity or major neonatal complications such as respiratory distress syndrome or intraventricular hemorrhage.</td>

<td><strong>34.</strong> Bora SA, Papageorghiou AT, Bottomley C, Kirk E, Bourne T. Reliability of transvaginal ultrasonography at 7–9 weeks' gestation in the determination of chorionicity and amnionicity in twin pregnancies. <em>Ultrasound Obstet Gynecol.</em> 2008;32(5):618-621.</td>
<td>Observational-Dx</td>
<td>67 twin pregnancies</td>
<td>To assess the agreement in the diagnosis of chorionicity and amnionicity between transvaginal US examination at 7–9 weeks’ gestation and at the 11–14–week transabdominal scan.</td>
<td>Chorionicity and amnionicity were documented in 67 viable twin pregnancies at both 7–9 and 11–14 weeks’ gestation. There was agreement in the chorionicity and amnionicity reported at each of the 2 scans in 65 out of 67 (97%) cases. Of the dichorionic-diamniotic pregnancies reported at 7–9 weeks, 53 out of 54 (98%) were confirmed at the 11–14–week scan and 1 (2%) was found to be MCDA. However, at birth these twins were of different sex, confirming dichorionic-diamniotic twins as initially diagnosed at 7–9 weeks. Of the 12 pregnancies diagnosed as MCDA at 7–9 weeks, all were found to be MCDA at the 11–14–week scan. There was 1 monochorionic-monoamniotic pregnancy diagnosed at 7–9 weeks that was subsequently found to be MCDA at the 11–14–week scan.</td>

<td>46. D’Antonio F, Khalil A, Dias T, Thilaganathan B. Crown-rump length discordance and adverse perinatal outcome in twins: analysis of the Southwest Thames Obstetric Research Collaborative (STORK) multiple pregnancy cohort. Ultrasound Obstet Gynecol. 2013;41(6):621-626.</td>
<td>Observational-Dx</td>
<td>2155 twin pregnancies</td>
<td>To determine the association between CRL discordance and adverse perinatal outcome in twin pregnancies.</td>
<td>A total of 2155 twin pregnancies were analyzed, of which 420 were monochorionic and 1735 dichorionic. There were 42 fetal losses before 24 weeks’ gestation and 23 perinatal deaths. CRL discordance was poorly predictive for fetal loss at &lt;24 weeks (AUC, 0.54 (95% CI, 0.46–0.62)), perinatal loss (AUC, 0.52 (95% CI, 0.41–0.64)), BWD (AUC, 0.61 (95% CI, 0.56–0.65)), birthweight &lt; 5(th) centile (AUC, 0.56 (95% CI, 0.53–0.59)), EFW discordance (AUC, 0.55 (95% CI, 0.51–0.60)) and preterm birth at &lt;34 weeks (AUC, 0.50 (95% CI, 0.47–0.54)). Overall mortality was significantly higher in monochorionic (5.0%) than in dichorionic (2.6%) twins (P=0.016). Logistic regression analysis demonstrated that chiorionicity (OR 2.09 (95% CI, 1.06–4.10); P=0.033) independently contributed to determining mortality, while CRL discordance (P=0.201) did not. Adjusting for chorionicity did not improve the detection of adverse outcomes using CRL discordance.</td>

</tr>
<tr>
<td>48. Weissmann-Brenner A, Weisz B, Achiron R, Shrim A. Can discordance in CRL at the first trimester predict birth weight discordance in twin pregnancies? <em>J Perinat Med.</em> 2012;40(5):489-493.</td>
<td>Observational-Dx</td>
<td>792 fetuses</td>
<td>To examine the correlation between measurements of CRL, NT, and birth weight in dichorionic and monochorionic twin pregnancies.</td>
<td>The study population comprised 792 fetuses: 94 MCDA and 698 dichorionic/diamniotic. Maternal age, gestational age at delivery, birth weight, and birth length were all significantly higher for the dichorionic group. Male fetuses had significantly higher NT and higher birth weight than female fetuses. Discordance in CRL was found to correlate with discordance in birth weight in the entire study population (<em>P</em>&lt;0.0001, <em>R</em>=0.25), in the dichorionic twins (<em>P</em>&lt;0.0001, <em>R</em>=0.275), but not in monochorionic twins (<em>R</em>=0.10, <em>P</em>=0.33). CRL discordance above the 90th percentile (&gt;12%) predicted 14/40 pregnancies with BWD above the 90th percentile (&gt;24%) (<em>P</em>&lt;0.001, likelihood ratio =4.1 (2.6–6.2)). CRL discordance above the 95th percentile (&gt;16%) predicted 5/21 pregnancies with BWD above the 95th percentile (&gt;30%) (<em>P</em>&lt;0.001, likelihood ratio =5.5 (2.6–10.4)). NT discordance was correlated with CRL discordance (<em>R</em>=0.15, <em>P</em>&lt;0.0001), but not with birth weight, regardless of chorionicity or gender.</td>

<td>52. Spencer K, Nicolaides KH. Screening for trisomy 21 in twins using first trimester ultrasound and maternal serum biochemistry in a one-stop clinic: a review of three years experience. <em>Bjog.</em> 2003;110(3):276-280.</td>
<td>Observational-Dx</td>
<td>230 twin pregnancies</td>
<td>To evaluate the performance of screening for fetal trisomy 21 in the first trimester of twin pregnancies by a combination of maternal serum biochemistry and US.</td>
<td>Overall, 97.4% of the women with twins (224/230) accepted first trimester screening. The rate of detection of trisomy 21 was 75% (3/4). Fetal death at presentation was found in 3.4% of fetuses (16/460). Of women who accepted screening, 4.3% (10/230) presented too late for fetal NT measurement and 10.0% of women (23/230) presented too early. A risk for trisomy 21 was calculated for each fetus based on the individual fetal NT thickness and the maternal biochemistry. The false positive rate among those eligible for first trimester screening was 9.0% (19/206) of pregnancies and 6.9% of fetuses (28/412). Uptake of invasive testing was 59% (10/17) with chorionic villus sampling in 8 cases and amniocentesis in 2. No fetal loss occurred within 28 days of chorionic villus sampling and no loss occurred after amniocentesis. 1 case of trisomy 21 was identified for every 3 invasive procedures.</td>

<td>Review/Other-Dx</td>
<td>N/A</td>
<td>To combine the US marker NT with serum markers so that they can be used together in prenatal screening for Down syndrome in twin pregnancies.</td>
<td>For monochorionic twin pregnancies (taken as monozygous), the 2 fetus-specific NT measurements are averaged before risk is calculated and before the contribution of the serum markers is incorporated. For dichorionic twin pregnancies (taken as dizygous), the risk for each fetus based on the individual NT measurements is calculated, the 2 fetus-specific risks are added together, and then the contribution of the serum markers is incorporated. In this way, all the screening markers can be used in combination to produce a pregnancy-specific “pseudo-risk”, rather than a fetus-specific pseudo-risk. We refer to pseudo-risk because in the absence of sufficient data on the screening markers in affected twin pregnancies, a true risk estimate cannot be calculated. Tentative estimates are given of screening performance in twins using NT, the combined test (NT with first-trimester serum markers), and the integrated test (NT with first- and second-trimester serum markers), all interpreted with maternal age.</td>

<td>56. Sebire NJ, D’Ercole C, Hughes K, Carvalho M, Nicolaides KH. Increased nuchal translucency thickness at 10–14 weeks of gestation as a predictor of severe twin-to-twin transfusion syndrome. <em>Ultrasound Obstet Gynecol.</em> 1997;10(2):86-89.</td>
<td>Observational-Dx</td>
<td>132 twin pregnancies</td>
<td>To examine a possible association between increased NT thickness at 10–14 weeks of gestation in monochorionic twin pregnancies and the subsequent development of severe TTTS.</td>
<td>In 132 monochorionic twin pregnancies, including 16 that developed severe TTTS at 15–22 weeks of gestation and 116 that did not develop TTTS, CRL, NT thickness and fetal heart rate were measured at 10–14 weeks. In those that developed severe TTTS, the prevalence of NT thickness above the 95th centile of the normal range and the intertwin difference in NT thickness and fetal heart rate were significantly higher than in the non-TTTS group; there were no significant differences between the groups in the intertwin difference in CRL. For fetal NT above the 95th centile, the positive and negative predictive values for the development of TTTS were 38% and 91%, respectively; the likelihood ratios of NT above or below the 95th centile for the development of severe TTTS were 4.4 (1.8–9.7) and 0.7 (0.4–0.9), respectively.</td>

<td>Observational-Dx</td>
<td>267 twin pregnancies</td>
<td>To determine perinatal outcomes of twin pregnancies discordant for a major fetal anomaly and to compare with twins without anomaly.</td>
<td>There were 48 cases of MCDA, 2 cases of monochorionic monoamniotic and 217 twins with dichorionic placentation. Out of 267 twin pregnancies, there were 17 (6.3%) twins with fetal anomaly. Twins discordant for a major fetal anomaly were diagnosed in 13 cases (4.8%). We observed 3 cases with MCDA and 10 cases with dichorionic placentation and the incidence of discordance for a major fetal anomaly as 4.6% (10/217) in dichorionic and 6.0% (3/50) in monochorionic twin pregnancies. We identified 8 cases (62%) with craniospinal, 2 (15%) with gastrointestinal, 2 (15%) with urinary system, and 1 case (8%) with both craniospinal and gastrointestinal anomalies. There were significant differences between the normal co-twin of the major anomaly group (n = 13) and twins without anomaly group (n = 235) in mean gestational age at delivery (32 vs 34 weeks; P=0.029), mean birth weight (1,640 vs 2,030 g; P=0.022) and perinatal survival rate (69.2 vs 91.1%; P=0.018), respectively.</td>

<td>Observational-Dx</td>
<td>630 placentas</td>
<td>To study the association between VCI and different outcomes in monochorionic twins with and without TTTS.</td>
<td>A total of 630 monochorionic placentas with TTTS (n = 304) and without TTTS (n = 326) were studied. The incidence of VCI in the TTTS and non-TTTS group was 36.8% and 35.9%, respectively (<em>P</em>=0.886). The presence of VCI in 1 twin was significantly associated with small for gestational age status (OR [OR] 1.45, 95% CI 1.13, 1.87) and severe BWD (OR 3.09, 95% CI 1.93, 4.96). Our results also showed significant interaction between TTTS and VCI when we considered IUFD and gestational age at birth. The prevalence of IUFD in monochorionic pregnancies without TTTS increased from 4.6% to 14.1% in the presence of VCI (<em>P</em>=0.027). In the TTTS group, the prevalence of IUFD was comparable in the absence or presence of VCI. Similarly, gestational age at birth was significantly lower in the presence of VCI only in the non-TTTS group.</td>

<td>71. Vayssiere C, Favre R, Audibert F, et al. Cervical length and funneling at 22 and 27 weeks to predict spontaneous birth before 32 weeks in twin pregnancies: a French prospective multicenter study. Am J Obstet Gynecol. 2002;187(6):1596-1604.</td>
<td>Observational-Dx</td>
<td>466 pregnant women</td>
<td>To determine the accuracy of cervical length and funneling of the internal os in the prediction of the spontaneous very preterm birth of twin pregnancies.</td>
<td>The median gestational age at delivery was 36 weeks in both populations. Of the population that was included at 22 weeks of gestation, 5.2% (13 women) gave birth spontaneously before 32 weeks of gestation, and 13.2% (33 women) gave birth spontaneously before 35 weeks of gestation; the median cervical length was 40 mm. The receiver operating characteristic curve showed no clear best cutoff point for cervical length. For spontaneous delivery before 32 and 35 weeks of gestation, the sensitivity of cervical length (\leq 30 \text{ mm} ) was 46% and 27%, respectively; the specificity was 89% and 90%, respectively. The sensitivity of funneling was 54% and 33%, and its specificity 89% and 91%, respectively. After multivariate analysis, only funneling remained significant for delivery before both 32 and 35 weeks of gestation. Of the population that was included at 27 weeks, 3.3% (7 women) gave birth spontaneously before 32 weeks of gestation, and 12.4% (26 women) gave birth spontaneously before 35 weeks of gestation; the median cervical length was 35 mm. The receiver operating characteristic curve showed 25 mm to be the best cutoff point for cervical length. For spontaneous delivery before 32 and 35 weeks of gestation, the sensitivity of cervical length (\leq 25 \text{ mm} ) was 100% and 54%, respectively, and the specificity was 84% and 87%, respectively. The sensitivity of funneling was 86% and 54%, and the specificity 78% and 82%, respectively. After multivariate analysis, both indicators remained significant for delivery before 35 weeks of gestation. Funneling after transfundal pressure at 22 or 27 weeks did not predict very preterm delivery.</td>

<td>85. Kilby MD, Govind A, O'Brien PM. Outcome of twin pregnancies complicated by a single intrauterine death: a comparison with viable twin pregnancies. Obstet Gynecol. 1994;84(1):107-109.</td>
<td>Observational-Dx</td>
<td>342 twin births</td>
<td>To examine the perinatal and maternal outcomes in twin pregnancies when a single intrauterine death occurs.</td>
<td>Of a total 34,804 live deliveries, 342 were documented as twin births at a gestation of &lt;20 weeks (incidence 0.98%). Of the twin pregnancies over this period, 20 (5.85%) were complicated by a single intrauterine death. There was an increase in the incidence of congenital structural abnormalities among those twins dying in utero as compared to uneventful twin pregnancies (25% vs 0.3%; P&lt;.001). A significant proportion of these twin pregnancies had monochorial placentas (35% vs 9%; P&lt;.001) and were admitted to special care units (70% vs 5.6%; P&lt;.001) as compared to the normal twin sample. Maternal morbidity has previously been described as being increased. Although there was an increased risk of nonproteinuric and mild pregnancy-induced hypertension, no adverse maternal effects of conservative management were noted in this study.</td>

<td>86. Ong SS, Zamora J, Khan KS, Kilby MD. Prognosis for the co-twin following single-twin death: a systematic review. <em>Bjog</em>. 2006;113(9):992-998.</td>
<td>Review/Other-Dx</td>
<td>28 studies</td>
<td>To determine the incidence of a) co-twin death, b) neurological abnormality and c) preterm delivery for the surviving co-twin following single-twin death after 14 weeks of gestation.</td>
<td>The search strategy yielded 632 potentially relevant citations. Full manuscripts were retrieved for 54 citations and 28 studies were finally included in the review. Following the death of 1 twin, the risk of monochorionic and dichorionic co-twin demise was 12% (95% CI, 7–11) and 4% (95% CI, 2–7), respectively. The risk of neurological abnormality in the surviving monochorionic and dichorionic co-twin was 18% (95% CI, 11–26) and 1% (95% CI, 0–7), respectively. The risk of preterm delivery was 68% (95% CI, 56–78) and 57% (95% CI, 34–77), respectively. Where there was comparative data within studies, the odds of monochorionic co-twin intrauterine death was 6 times that of dichorionic twins (OR 6.04 [95% CI, 1.84–19.87]). Neurological abnormality was also higher in monochorionic compared with dichorionic pregnancies (OR 4.07 [95% CI, 1.32–12.51]).</td>

<td>87. Almog B, Levin I, Wagman I, et al. Adverse obstetric outcome for the vanishing twin syndrome. <em>Reprod Biomed Online</em>. 2010;20(2):256-260.</td>
<td>Observational-Dx</td>
<td>399 patients</td>
<td>To compare obstetric outcomes of in vitro fertilization singleton pregnancies diagnosed with vanishing twin syndrome with those pregnancies originating as singleton pregnancies and with twin pregnancies.</td>
<td>Mean gestational age was 35.1+/-3.7 vs 38.2+/-2.6 weeks (P=0.001) for patients and singleton controls respectively. Birth weights were 2834.4+/-821.2 vs 3036+/-489.3g (P=0.02), proportion of low birth weight (&lt;2500 g) was 33.3% vs 11.7% (P=0.0001) and very low birth weight (&lt;1500 g) 3.5 vs 0.6% for patients and singleton controls respectively. The proportion of deliveries before 28 weeks of gestation was 7.0% vs 1.2% (P=0.01) for patients and singleton controls respectively. When comparing the study group to twin control pregnancies, a similar gestational age at delivery (35 weeks) and rate of preterm birth (23%) were found.</td>

<td>Observational-Dx</td>
<td>252,994 deliveries</td>
<td>To evaluate whether vanishing twin syndrome is associated with adverse perinatal outcome.</td>
<td>During the study period, 278 pregnancies with vanishing twin syndrome were compared with 1,801 pregnancies of dichorionic twins and 252,994 pregnancies of singletons. A significant linear association was documented among the 3 groups and various adverse outcomes, including gestational diabetes mellitus, IUGR, very low birth weight, and perinatal mortality. The higher risk was noted in the vanishing twin syndrome group, and the lowest in singletons. Using multivariable logistic regression models, while controlling for confounders such as fertility treatment and maternal age, vanishing twin syndrome (as compared with singletons) was found to be an independent risk factor for several adverse perinatal outcomes including gestational diabetes mellitus, IUGR, very low birth weight, low Apgar scores, and perinatal mortality (adjusted ORs with their respective 95% CIs, 1.4 [1.01–2.0], 2.7 [1.7–4.3], 6.9 [4.7–10.2], 1.9 [1.1–3.3], 2.4 [1.2–4.5]).</td>

<td>Observational-Dx</td>
<td>128,168 twin sets</td>
<td>To estimate the association between BWD and neonatal mortality controlling for the effects of fetal growth, and to understand the differences in the incidence of mortality between larger and smaller infants.</td>
<td>Mortality was 11 times higher among highly discordant smaller twins (30% or more) compared with nondiscordant smaller twins (43.4 and 3.8 per 1000, respectively). Risk estimates ranged from 1.08 (95% CI, 0.85, 1.38) among 15%–19% discordant twins to 2.05 (95% CI, 1.66, 2.51) among 30% or more discordant twins. Larger twins had similar risk estimates. After accounting for the association between fetal growth and discordance, mortality risk was substantially higher among smaller and larger twins who were highly discordant (30% or more). In addition, there was little difference in the magnitude of risk estimates between highly discordant smaller and larger twins.</td>

<td>90. Kato N, Matsuda T. Estimation of optimal birth weights and gestational ages for twin births in Japan. <em>BMC Public Health.</em> 2006;6:45.</td>
<td>Review/Other-Dx</td>
<td>10,302,465 pregnancies</td>
<td>To estimate the birth weight and gestational age associated with the lowest perinatal death rate in contemporary Japan.</td>
<td>The overall perinatal mortality rates per 1,000 births for singletons was 6.9, and the lowest perinatal mortality rates was 1.1 for birth weight (3.5–4.0 kg) and gestational age (40–weeks). For twins, the overall perinatal mortality rates per 1,000 births was 36.8, and the lowest perinatal mortality rates was 3.9 for birth weight (2.5–3.0 kg) and gestational age (36–39 weeks). At optimal birth weight and gestational age, the perinatal mortality rates were reduced to 15.9% for singletons, and 10.6% for twins, compared to the overall perinatal mortality rates. The risk of perinatal mortality was greater in twins than in singleton sat the same deviation from the ideal category of each plurality.</td>

<td>91. Banks CL, Nelson SM, Owen P. First and third trimester ultrasound in the prediction of birthweight discordance in dichorionic twins. <em>Eur J Obstet Gynecol Reprod Biol.</em> 2008;138(1):34-38.</td>
<td>Observational-Dx</td>
<td>135 gestations</td>
<td>To assess the efficacy of routine third trimester US fetal biometry, third trimester fetal growth velocity and first trimester differences in size in the prediction of subsequent birthweight discordance.</td>
<td>135 dichorionic gestations were identified over a consecutive 3–year-period. 108 twin gestations had both CRL and sufficient US measurements in the third trimester to calculate fetal growth velocity. 26 pregnancies (24%) had discordant birthweight. Only EFW Z score difference was correlated with birthweight disparity (r=0.36, ( P \leq 0.001 )). An EFW Z score difference of 0.6 had an AUC of 0.70 (95% CI, 0.59–0.79) but this did not differ significantly from first trimester prediction of growth discordance which had an area of 0.55 (95% CI, 0.44–0.66). The likelihood ratio for first and third trimester prediction of discordance were low.</td>

<td>93. Danon D, Melamed N, Bardin R, Meizner I.</td>
<td>Observational-Dx</td>
<td>1112 pregnancies</td>
<td>To compare the accuracy of fetal weight estimations between normal and growth-restricted twin and singleton pregnancies in a single tertiary center.</td>
<td>The study groups included 278 twins and 834 singleton pregnancies. The twins group was characterized by a higher mean absolute percentage error compared with the singleton group (8.9% compared with 6.8%). Accuracy was lower for the second twins than for the first twins. When comparing the subgroup of fetal growth restriction, differences in sensitivity and specificity were small for singleton compared with overall twins (47.5% compared with 48.9% and 97.7% compared with 95.7%, respectively). Overall accuracy was better in the singleton group (95% compared with 88%), mainly due to relatively low accuracy in the second twin (86%). For detection of discordancy, EFW had a sensitivity of 52%, specificity of 88%, and overall accuracy of 81%.</td>
</tr>
<tr>
<td>94. Diaz-Garcia C, Bernard JP, Ville Y, Salomon LJ.</td>
<td>Observational-Dx</td>
<td>283 twin pregnancies</td>
<td>To assess the accuracy of EFW in twins and to assess the accuracy of US examination to predict BWD.</td>
<td>283 twin pregnancies were included. Mean and SD (%) of the standardized errors were 1.54 +/- 12.19, 0.19 +/- 11.87, 10.93 +/- 15.55, - 1.91 +/- 14.93 and 5.37 +/- 14.91 for Hadlock1, Hadlock2, Shepard, Ong and Warsof formulas, respectively. Hadlock2’s formula allowed for the highest proportion of newborns with birthweight within 10% of EFW and it also performed best to predict discordance of more than 25% as assessed by AUC.</td>
</tr>
<tr>
<td>95. Gonzalez-Quintero VH, Luke B, O'Sullivan MJ, et al.</td>
<td>Observational-Dx</td>
<td>3910 twin gestations</td>
<td>To evaluate factors that are associated with significant BWD.</td>
<td>Severe BWD was associated with fetal growth deceleration by 20 to 28 weeks (adjusted OR, 4.90; 95% CI, 3.15–7.64) and between 28 weeks to birth (adjusted OR, 3.48; 95% CI, 1.72–7.06). Antenatal bleeding (adjusted OR, 1.86; 95% CI, 1.08–3.21), preeclampsia (adjusted OR, 1.70, 95% CI, 1.21–2.41), and monochorionicity (adjusted OR, 2.35, 95% CI, 1.71–3.23) were also associated with BWD.</td>

Evidence Table Key

Study Quality Category Definitions

- **Category 1**  The study is well-designed and accounts for common biases.
- **Category 2**  The study is moderately well-designed and accounts for most common biases.
- **Category 3**  There are important study design limitations.
- **Category 4**  The study is not useful as primary evidence. The article may not be a clinical study or the study design is invalid, or conclusions are based on expert consensus. For example:
  a)  the study does not meet the criteria for or is not a hypothesis-based clinical study (e.g., a book chapter or case report or case series description);
  b)  the study may synthesize and draw conclusions about several studies such as a literature review article or book chapter but is not primary evidence;
  c)  the study is an expert opinion or consensus document.
- **M = Meta-analysis**

Dx = Diagnostic

Tx = Treatment
