<td>2. Moschos E, Twickler DM. Endometrial thickness predicts intrauterine pregnancy in patients with pregnancy of unknown location. Ultrasound Obstet Gynecol. 2008;32(7):929-934.</td>
<td>Observational-Dx</td>
<td>591 patients; complete data available for 517 patients</td>
<td>To determine whether endometrial thickness and other parameters are useful predictors of normal IUP in the setting of vaginal bleeding and sonographic diagnosis of pregnancy of unknown location.</td>
<td>4 variables (maternal age, estimated gestational age by last menstrual period, endometrial thickness and serum beta-hCG) were significant in the prediction of normal IUP (area under the ROC curve = 0.86). As maternal age, estimated gestational age by last menstrual period and beta-hCG increased, the likelihood of a normal IUP decreased, while as the endometrial thickness increased, the likelihood of a normal IUP increased. For each millimeter increase in endometrial thickness, the odds increased by 27% that the patient would have a normal IUP. No normal IUP had an endometrial thickness &lt;8 mm.</td>

<tr>
<td>3. Seeber B, Sammel M, Zhou L, Hummel A, Barnhart KT. Endometrial stripe thickness and pregnancy outcome in first-trimester pregnancies with bleeding, pain or both. J Reprod Med. 2007;52(9):757-761.</td>
<td>Observational-Dx</td>
<td>576 patients</td>
<td>To determine the association between endometrial stripe thickness and pregnancy outcome in women with a symptomatic first-trimester pregnancy and to determine how vaginal bleeding, pelvic pain and hCG level affect endometrial stripe thickness.</td>
<td>Endometrial stripe was thinner with increased vaginal bleeding and associated with hCG level and pregnancy outcome. The mean endometrial stripe for ectopic pregnancies was 9.56 +/- 4.87, for IUPs was 12.12 +/- 6.0 and for spontaneous abortion was 10.19 +/- 6.10. 99% of patients with ectopic pregnancies had an ES &lt;21 mm, and 100% had one ≤25 mm.</td>

<tr>
<td>8. Mehta TS, Levine D, Beckwith B. Treatment of ectopic pregnancy: is a human chorionic gonadotropin level of 2,000 mIU/mL a reasonable threshold? <em>Radiology</em>. 1997;205(2):569-573.</td>
<td>Observational-Dx</td>
<td>676 patients</td>
<td>Retrospective study to determine whether a hCG level of 2,000 mIU/mL is a reasonable threshold for diagnosing ectopic pregnancy in the absence of US findings of IUP and thus to prevent inappropriate treatment that will result in the loss of an otherwise normal pregnancy in women with early IUP.</td>
<td>548 patients had evidence of a normal or abnormal IUP. 51 patients (40%) of the 128 patients without evidence of an IUP had an hCG level &gt;2,000 mIU/mL. Of these 51 patients, 15 (29%) were treated for ectopic pregnancy; 17 (33%) were not immediately treated for ectopic pregnancy and had a normal IUP at follow-up US. An hCG level of 2,000 mIU/mL without US findings of IUP, while suggestive of an abnormal pregnancy, is not diagnostic. Per the results of recent studies, it is reasonable to closely follow-up rather than treat many of these early, stable cases of ectopic pregnancy.</td>

<td>9. Barnhart KT, Fay CA, Suescum M, et al. Clinical factors affecting the accuracy of ultrasonography in symptomatic first-trimester pregnancy. <em>Obstet Gynecol.</em> 2011;117(2 Pt 1):299-306.</td>
<td>Observational-Dx</td>
<td>1,880 women</td>
<td>To evaluate factors associated with accuracy of initial US in patients with symptomatic first-trimester pregnancy.</td>
<td>1,880 women were evaluated. Overall accuracy of initial US diagnosis was 78%. A probable US diagnosis of ectopic pregnancy (adnexal mass without the presence of a yolk sac or embryo) resulted in a higher sensitivity (42.1% compared with 13.2%; <em>P</em>&lt;.001) but a lower PPV (82.7% compared with 98%; <em>P</em>&lt;.01) compared with a definite diagnosis. A probable US diagnosis of IUP (double decidual sign without yolk sac or embryo) resulted in a higher sensitivity (36.0% compared with 4.0%; <em>P</em>&lt;.001) and lower PPV (58.8% compared with 87.0%; <em>P</em>&lt;.001) compared with a definite diagnosis. The sensitivity (34.3% compared with 75.9%; <em>P</em>&lt;.01) and PPV (80.4% compared with 91.5%; <em>P</em>=.02) were lower for diagnosis of ectopic pregnancy when serum hCG level was &lt;2,000 mIU/mL. US was less accurate when bleeding was the chief complaint (72.7% compared with 84.8% <em>P</em>&lt;.006) but not substantially altered by pain as a chief complaint (78.0% compared with 77.8% <em>P</em>&gt;.99).</td>

<tr>
<td>10. Connolly A, Ryan DH, Stuebe AM, Wolfe HM. Reevaluation of discriminatory and threshold levels for serum beta-hCG in early pregnancy. <em>Obstet Gynecol.</em> 2013;121(1):65-70.</td>
<td>Review/Other-Dx</td>
<td>651 pregnancies</td>
<td>To reevaluate both discriminatory and threshold levels associated with visualization of gestational sacs, yolk sacs, and fetal poles in patients presenting with vaginal bleeding, pain, or vaginal bleeding and pain in the first trimester of pregnancy using current US technology.</td>
<td>651 pregnancies met inclusion criteria; 366 were viable. Discriminatory beta-hCG levels at which structures would be predicted to be seen 99% of the time were 3,510 mIU/mL, 17,716 mIU/mL, and 47,685 mIU/mL for gestational sac, yolk sac, and fetal pole, respectively. In this population, threshold values for beta-hCG levels at which these structures could be seen were 390 mIU/mL, 1,094 mIU/mL, and 1,394 mIU/mL, respectively.</td>

<td>14. Crochet JR, Bastian LA, Chireau MV. Does this woman have an ectopic pregnancy?: the rational clinical examination systematic review. <em>JAMA</em>. 2013;309(16):1722-1729.</td>
<td>Review/Other-Dx</td>
<td>14 studies with 12,101 patients</td>
<td>To systematically review the accuracy and precision of the patient history, clinical examination, readily available laboratory values, and sonography in the diagnosis of ectopic pregnancy in women with abdominal pain or vaginal bleeding during early pregnancy.</td>
<td>All components of the patient history had a LR+ &lt;1.5. The presence of an adnexal mass in the absence of an IUP on TVU (LR+ 111; 95% CI, 12-1028; n = 6,885), and the physical examination findings of cervical motion tenderness (LR+ 4.9; 95% CI, 1.7–14; n = 1,435), an adnexal mass (LR+ 2.4; 95% CI, 1.6–3.7; n = 1,378), and adnexal tenderness (LR+ 1.9; 95% CI, 1.0–3.5; n = 1,435) all increase the likelihood of ectopic pregnancy. A lack of adnexal abnormalities on TVU (LR- 0.12; 95% CI, 0.03–0.55; n = 6,885) decreases the likelihood of ectopic pregnancy. Existing studies do not establish a single serum hCG level that is diagnostic of ectopic pregnancy.</td>

<tr>
<td>19. Romosan G, Bjartling C, Skoog L, Valentin L. Ultrasound for diagnosing acute salpingitis: a prospective observational diagnostic study. <em>Hum Reprod.</em> 2013;28(6):1569-1579.</td>
<td>Observational-Dx</td>
<td>52 patients</td>
<td>Aim of study is (i) to describe US findings in cases of acute mild, moderate and severe salpingitis verified by laparoscopy and (ii) to estimate the sensitivity and specificity of TVU for diagnosing acute salpingitis in patients with clinical signs of PID.</td>
<td>Of the 52 patients, 23 (44%) had a final diagnosis unrelated to genital infection, while the other 29 had cervicitis (n = 3), endometritis (n = 9) or salpingitis (n = 17; mild n = 4, moderate n = 8, severe, ie, pyosalpinx n = 5). Bilateral adnexal masses and bilateral masses lying adjacent to the ovary were seen more often on US in patients with salpingitis than with other diagnoses (bilateral adnexal masses: 82 vs 17%, ie, 14/17 vs 6/35, P=0.000, positive LR 4.8, negative LR 0.22; bilateral masses adjacent to ovary: 65 vs 17%, ie, 11/17 vs 6/35, P=0.001, positive LR 3.8, negative LR 0.42). In cases of salpingitis, the masses lying adjacent to the ovaries were on average 2–3 cm in diameter, solid (n = 14), unilocular cystic (n = 4), multilocular cystic (n = 3) or multilocular solid (n = 1), with thick walls and well vascularized at color Doppler. No case were the cogwheel sign or incomplete septae seen. All 13 cases of moderate or severe salpingitis were diagnosed with US (detection rate 100%, 95% CI, 78%–100%) compared with 1 of 4 cases of mild salpingitis. 3 of 6 cases of appendicitis, and 2 of 2 ovarian cysts were correctly diagnosed with US, and 1 case of adnexal torsion was suspected and then verified at laparoscopy.</td>

<td>21. Mashiach R, Melamed N, Gilad N, Ben-Shitrit G, Meizner I. Sonographic diagnosis of ovarian torsion: accuracy and predictive factors. <em>J Ultrasound Med.</em> 2011;30(9):1205-1210.</td>
<td>Observational-Dx</td>
<td>63 women</td>
<td>To determine the accuracy of sonographic diagnosis of ovarian torsion and the predictive value of typical sonographic signs.</td>
<td>Sonography had diagnostic accuracy of 74.6% for ovarian torsion. Abnormal ovarian blood flow and the presence of free fluid were the most diagnostically accurate isolated sonographic signs (PPVs, 80.0% and 89.2%, respectively; NPVs, 46.2% and 46.2%). Using combinations of sonographic signs yielded higher specificity and PPVs and lower sensitivity and NPVs for ovarian torsion. The diagnostic accuracy was largely affected by the US operator (mean +/- SD, 78.8% +/- 16.0%; range, 60.0%–100%).</td>

<td>Review/Other-Dx</td>
<td>25 women</td>
<td>To identify the different sonographic markers on gray scale and color Doppler sonography in TOAs.</td>
<td>Presence of a mass was found in all cases. The maximum diameter of the mass was 5 cm in 2 cases and between 5 cm and 10 cm in 23 cases. The mass was demonstrated at the anatomic position of the ovary in 21 cases (84%) and at the cul-de-sac in 4 cases (16%). The mass was a simple cyst in 2 cases (8%), in 4 cases it was cystic with diaphragms (16%), in 4 cases it was a thickened tube-shaped structure with multiple internal echoes (16%) and in 15 cases it was a mixture of cystic and solid elements (60%). Pyosalpinges with fluid-fluid levels were found in 2 cases. Fluid in the cul-de-sac was observed at a rate of 48%. Color Doppler sonography demonstrated abundant blood flow in the borders and the septa of the TOAs.</td>

<tr>
<td>27. Chiou SY, Lev-Toaff AS, Masuda E, Feld RL, Bergin D.</td>
<td>Observational-Dx</td>
<td>58 patients</td>
<td>To review the clinical, imaging, and pathologic findings associated with adnexal torsion. Imaging reports were assessed to determine whether a correct preoperative diagnosis was made.</td>
<td>Common imaging findings were adnexal mass (65% on US, 87% on CT, and 75% on MRI), a displaced adnexal mass/enlarged ovary (53% on US, 87% on CT, and 75% on MRI), and ascites (53% on US, 73% on CT, and 50% on MRI). A correct preoperative diagnosis was made by initial US in 15 (71%) of 21 cases vs initial CT in 5 (38%) of 13. A correct imaging diagnosis was made more frequently in premenopausal than in menopausal patients (( P=.02 )) and in patients without an underlying adnexal mass compared with those with a mass (( P=.05 )). Although CT shows features suggestive of torsion, the diagnostic value of initial CT was less than that of initial US in this study.</td>

<td>36. Lehnert BE, Gross JA, Linnau KF, Moshiri M. Utility of ultrasound for evaluating the appendix during the second and third trimester of pregnancy. <em>Emerg Radiol.</em> 2012;19(4):293-299.</td>
<td>Observational-Dx</td>
<td>99 consecutive pregnant women</td>
<td>To retrospectively evaluate the right lower quadrant USs in women presenting during the second or third trimester of pregnancy for the frequency of appendix visualization and accuracy in diagnosing appendicitis.</td>
<td>The appendix was not visualized in 97% (96/99) of right lower quadrant US examinations. Of the 3 studies in which the appendix was visualized, 2 were considered positive for appendicitis and 1 was considered negative. 8 patients in this group ultimately underwent appendectomy, including the 2 patients with positive right lower quadrant USs, and appendicitis confirmed at pathology in 7 of these cases (87.5%). Right lower quadrant US successfully demonstrated an abnormal appendix in 28.7% (2 of 7) of surgically confirmed cases; however, this technique did not detect appendicitis in 71% (5 of 7) of patients with surgically proven disease due to nonvisualization of the appendix.</td>

<td>Sheafor DH, Hertzberg BS, Freed KS, et al. Nonenhanced helical CT and US in the emergency evaluation of patients with renal colic: prospective comparison. <em>Radiology.</em> 2000;217(3):792-797.</td>
<td>Observational-Dx</td>
<td>45 patients</td>
<td>Prospective comparison of nonenhanced helical CT and US for the depiction of urolithiasis.</td>
<td>Diagnoses included 23 ureteral calculi and 1 each of renal cell carcinoma, appendicitis, ureteropelvic junction obstruction, renal subcapsular hematoma, cholelithiasis, medullary calcinosis, and myelolipoma. CT depicted 22/23 ureteral calculi (sensitivity, 96%). US depicted 14/23 ureteral calculi (sensitivity, 61%). Differences in sensitivity were statistically significant (P=.02). Specificity for each technique was 100%. When modalities were compared for the detection of any clinically relevant abnormality (eg, unilateral hydronephrosis and/or urolithiasis in patients with an obstructing calculus), sensitivities of US and CT increased to 92% and 100%, respectively. One case of appendicitis was missed at US, whereas medullary calcinosis and myelolipoma were missed at CT.</td>

<td>Observational-Dx</td>
<td>318 patients</td>
<td>To prospectively assess ureteric obstructive uropathy using 3D US methods when the etiology of ureteral obstruction was proved difficult to evaluate with 2D US and plain radiography.</td>
<td>The study showed a high accuracy of detection of different levels of ureteric calcular obstruction; 99.1% in men and 96.7% in women. 3D XI technology proved more efficient in stone count (88.9%) than sectional planes and rendering method altogether (55.6%). The success rate of identifying obstructive uropathy due to inflammatory variants showed a perfect diagnostic value of 100%. Similar percentages could be obtained in cases secondary to neoplastic infiltration or permeation of the ureters. Cases compared with excretory urography revealed close correlation with 3D US and superiority of the latter when renal function physiologically altered in some cases of calcular obstructive uropathy.</td>

<td>45. Shetty MK, Garrett NM, Carpenter WS, Shah YP, Roberts C. Abdominal computed tomography during pregnancy for suspected appendicitis: a 5-year experience at a maternity hospital. <em>Semin Ultrasound CT MR.</em> 2010;31(1):8-13.</td>
<td>Observational-Dx</td>
<td>39 pregnant patients</td>
<td>To evaluate the role of CT in a pregnant patient with right lower quadrant pain in whom there was a clinical suspicion of acute appendicitis.</td>
<td>The sensitivity of CT in the diagnosis of appendicitis in the study group was 100%, compared with a sensitivity of 46.1% for US. CT provides an accurate diagnosis in patients suspected to have acute appendicitis and is of value in avoiding false negative exploratory laparatomy with its consequent risk of maternal and fetal mortality and morbidity. Although sonography is the preferred initial imaging modality as its lack of ionizing radiation, CT is more accurate in providing a timely diagnosis and its use is justified to reduce maternal mortality and mortality in patients with appendicitis.</td>

<td>69. Long SS, Long C, Lai H, Macura KJ. Imaging strategies for right lower quadrant pain in pregnancy. AJR Am J Roentgenol. 2011;196(1):4-12.</td>
<td>Review/Other-Dx</td>
<td>6 articles</td>
<td>To determine the best imaging technique to evaluate right lower quadrant pain in a pregnant patient.</td>
<td>MRI provides a valuable tool for the evaluation of pregnant patients with right lower quadrant pain and can help avoid unnecessary laparotomies and radiation exposure from CT. Because cases of the nonvisualized appendix on MRI pose a diagnostic difficulty, further studies are needed to improve imaging protocols to decrease the incidence of nonvisualized appendix.</td>

<td>Observational-Dx</td>
<td>33 pregnant patients</td>
<td>To compare the sensitivity, specificity, PPV, and NPV of US and MRI in evaluation of pregnant patients with a clinical suspicion of appendicitis.</td>
<td>5 of the 33 patients had pathologically-proven appendicitis. 4 of the 5 patients with appendicitis were correctly diagnosed at MRI while 1 was interpreted as indeterminate (appendix not seen). At US, 1 was correctly diagnosed, 1 was incorrectly diagnosed as normal, and 3 were interpreted as indeterminate (appendix not seen). In 13 patients, a normal appendix was diagnosed at MRI, none of whom had appendicitis. In 3 patients, a normal appendix was diagnosed at US, 1 of whom had appendicitis. When the appendix was visualized at MRI, the sensitivity, specificity, PPV, and NPV for the diagnosis of appendicitis was 100% for all parameters. When the appendix was visualized at US, the sensitivity, specificity, PPV, and NPV for the diagnosis of appendicitis was 50%, 100%, 100%, and 66%, respectively.</td>

<tr>
<td>74.</td>
<td>Observational-Dx</td>
<td>79 patients</td>
<td>To determine whether MRI in pregnant patients with suspected appendicitis improves outcomes, minimizes length of stay, and lowers hospital charges.</td>
<td>79 patients were included in this study, 34 of whom had pathology-confirmed appendicitis. 31 patients underwent MRI. A trend toward fewer operations (OR, 0.45; 95% CI, 0.18–1.16; ( P = .07 )) was observed in the MRI group. 7 nontherapeutic explorations were performed in the non-MRI group and 1 nontherapeutic exploration in the MRI group (OR, 0.44; 95% CI, 0.08–2.32; ( P = .13 )). Patients in the MRI group were more frequently discharged from the emergency department (OR, 0.35; 95% CI, 0.13–0.94; ( P = .04 )) and had shorter length of stay (33.7 vs 64.8 hours, ( P &lt; .001 )). Gestational age, time to operation, and the presence of perforated appendicitis were similar between groups. No patient discharged without operation returned with appendicitis in either group. On multivariable analysis, the receipt of MRI (( P &lt; .001 )) and the absence of operative intervention (( P = .001 )) were associated with shorter length of stay. The mean hospital charges were similar in those with vs without appendicitis. One fetal loss occurred in the non-MRI group.</td>

<td>76. Pedrosa I, Lafonnara M, Pandharipande PV, Goldsmith JD, Rofsky NM. Pregnant patients suspected of having acute appendicitis: effect of MR imaging on negative laparotomy rate and appendiceal perforation rate. <em>Radiology.</em> 2009;250(3):749-757.</td>
<td>Observational-Dx</td>
<td>148; Mean gestational age, 20 weeks</td>
<td>To investigate the effect of MRI on the negative laparotomy rate and the perforation rate in pregnant patients suspected of having acute appendicitis and to assess the need for CT in this setting.</td>
<td>MRI results were positive in all 14 (10%) patients with acute appendicitis. MRI results were negative in 125/134 patients without acute appendicitis; there were 9 false-positive cases (2 positive, 7 inconclusive). Among the patients without acute appendicitis, the normal appendix could be visualized on MRI in 87% (116/134) of cases (P&lt;.0001). 27 (18%) patients underwent surgical exploration, and 8 of them had negative laparotomy results, yielding an negative laparotomy rate of 30% and a perforation rate of 21% (3/14 patients). Only 4 (3%) patients underwent CT. For pregnant patients clinically suspected of having acute appendicitis, use of MRI yields favorable combinations of negative laparotomy rate and perforation rate compared with previously reported values. The radiation exposure associated with CT examination can be avoided in most cases.</td>

<td>Observational-Dx</td>
<td>69 patients</td>
<td>To assess the diagnostic accuracy of static MRU in hydronephrosis and to compare parameters of hydronephrosis in MRU with IV urography.</td>
<td>The sensitivity and specificity MRU in detecting hydronephrosis were 95% and 100%, respectively. In determining the level of obstruction, the strength of agreement between IV urography and MRU using kappa statistics was kappa = 0.66, which corresponds to a good level of agreement. The Spearman correlation coefficient for the grade of hydronephrosis on MRU and IV urography was 0.92 (95% CI, 0.86–0.95), with a P&lt;.0001. The correct diagnosis was made in 89.2% of the cases by IV urography and in 93.8% of the cases by MRU.</td>

<td>79. Mullins JK, Semins MJ, Hyams ES, Bohlman ME, Matlaga BR. Half Fourier single-shot turbo spin-echo magnetic resonance urography for the evaluation of suspected renal colic in pregnancy. <em>Urology.</em> 2012;79(6):1252-1255.</td>
<td>Review/Other-Dx</td>
<td>9 pregnant women</td>
<td>To report the use of MRU in pregnant women suspected of having obstructing upper tract calculi.</td>
<td>The mean age of the subjects was 25 years (range 20–34); average gestational age of the fetus was 23 weeks (range 9–36). In all cases, a renal US was the initial imaging study obtained, with nondiagnostic findings. Half-Fourier acquisition single-shot turbo spin-echo MRU detected 4 ureteral stones and 4 cases of physiological hydronephrosis of pregnancy. In 1 case, interpretation of the MRU was limited as a result of patient motion. Of the patients with obstructing stones, 1 required endourologic management during her pregnancy and 3 were followed conservatively. No adverse events related to MRU occurred.</td>

<td>82. Torkzad MR, Bremme K, Hellgren M, et al. Magnetic resonance imaging and ultrasonography in diagnosis of pelvic vein thrombosis during pregnancy. <em>Thromb Res.</em> 2010;126(2):107-112.</td>
<td>Observational-Dx</td>
<td>27 patients</td>
<td>To evaluate the agreement between US and MRI in diagnosing the extent of DVT into the pelvic veins during pregnancy.</td>
<td>All 27 patients were imaged with both techniques at an average gestational age of 29 weeks (range 23–39). 3 cases (11.5%) of DVT in the pelvic veins were missed on US but detected by MRI. The upper limit of the DVT was always depicted at a higher (20 cases, 65.4%) or the same level (7 cases, 34.6%) on MRI than on US. Agreement expressed as kappa was 0.33 (95% CI, 0.27–0.40) demonstrating only fair agreement. In 1 woman the thrombus had propagated into the inferior vena cava, shown only on MRI.</td>

Evidence Table Key

Study Quality Category Definitions

- **Category 1**  The study is well-designed and accounts for common biases.
- **Category 2**  The study is moderately well-designed and accounts for most common biases.
- **Category 3**  There are important study design limitations.
- **Category 4**  The study is not useful as primary evidence. The article may not be a clinical study or the study design is invalid, or conclusions are based on expert consensus. For example:
  a) the study does not meet the criteria for or is not a hypothesis-based clinical study (e.g., a book chapter or case report or case series description);
  b) the study may synthesize and draw conclusions about several studies such as a literature review article or book chapter but is not primary evidence;
  c) the study is an expert opinion or consensus document.
- M = Meta-analysis

Dx = Diagnostic
Tx = Treatment

Abbreviations Key

- CI = Confidence interval
- CT = Computed tomography
- DVT = Deep venous thrombosis
- hCG = Human chorionic gonadotropin
- IUP = Intrauterine pregnancy
- IV = Intravenous
- LR = likelihood ratio
- MDCT = Multidetector computed tomography
- MRI = Magnetic resonance imaging
- MRU = Magnetic resonance urography
- MRV = Magnetic resonance venography
- NPV = Negative predictive value
- OR = Odds ratio
- PID = Pelvic inflammatory disease
- PPV = Positive predictive value
- ROC = Receiver-operating characteristic
- TOA = Tubo-ovarian abscess
- TVU = Transvaginal ultrasound
- US = Ultrasound
